

# 8-Bit LCD Flash Microcontroller with USB and XLP Technology

### **eXtreme Low-Power Features**

- Multiple Power Management Options for Extreme Power Reduction:
  - VBAT allows for lowest power consumption on back-up battery (with or without RTCC)
  - Deep Sleep allows near total power-down with the ability to wake-up on external triggers
  - Sleep and Idle modes selectively shut down peripherals and/or core for substantial power reduction and fast wake-up
- Alternate Clock modes Allow On-the-Fly Switching to a Lower Clock Speed for Selective Power Reduction
- Extreme Low-Power Current Consumption for Deep Sleep:
  - WDT: 650 nA @ 2V typical
  - RTCC: 650 nA @ 32 kHz, 2V typical
  - Deep Sleep current, 80 nA typical

### **Universal Serial Bus Features**

- USB V2.0 Compliant
- · Low Speed (1.5 Mb/s) and Full Speed (12 Mb/s)
- Supports Control, Interrupt, Isochronous and Bulk
  Transfers
- Supports up to 32 Endpoints (16 bidirectional)
- USB module can use Any RAM Location on the
- Device as USB Endpoint Buffers
- On-Chip USB Transceiver

#### **Peripheral Features**

- · LCD Display Controller:
  - Up to 60 segments by 8 commons
  - Internal charge pump and low-power, internal resistor biasing
  - Operation in Sleep mode
- Up to Four External Interrupt Sources
- Peripheral Pin Select Lite (PPS-Lite):
  - Allows independent I/O mapping of many peripherals
- Four 16-Bit and Four 8-Bit Timers/Counters with Prescaler
- Seven Capture/Compare/PWM (CCP) modules
- Three Enhanced Capture/Compare/PWM (ECCP) modules:
- One, two or four PWM outputs
- Selectable polarity
- Programmable dead time
- Auto-shutdown and auto-restart
- Pulse steering control

- Hardware Real-Time Clock/Calendar (RTCC):
   Runs in Deep Sleep and VBAT modes
- Two Master Synchronous Serial Ports (MSSP) modules Featuring:
  - 3-Wire/4-Wire SPI (all 4 modes)
  - SPI Direct Memory Access (DMA) channel w/1024 byte count
  - Two I<sup>2</sup>C modules Support Multi-Master/Slave mode and 7-Bit/10-Bit Addressing
- · Four Enhanced Addressable USART modules:
  - Support RS-485, RS-232 and LIN/J2602
  - On-chip hardware encoder/decoder for IrDA<sup>®</sup>
- Auto-wake-up on Auto-Baud Detect
- Digital Signal Modulator Provides On-Chip OOK, FSK and PSK Modulation for a Digital Signal Stream
- High-Current Sink/Source 18 mA/18 mA on all Digital I/O
- Configurable Open-Drain Outputs on ECCP/CCP/ USART/MSSP
- Extended Microcontroller mode Using 12, 16 or 20-Bit Addressing mode

### **Analog Features**

- 10/12-Bit, 24-Channel Analog-to-Digital (A/D) Converter:
  - Conversion rate of 500 ksps (10-bit), 200 kbps (12-bit)
  - Conversion available during Sleep and Idle
- Three Rail-to-Rail Enhanced Analog Comparators
   with Programmable Input/Output Configuration
- On-Chip Programmable Voltage Reference
- Charge Time Measurement Unit (CTMU):
   Used for capacitive touch sensing, up to 24 channels
  - Time measurement down to 1 ns resolution
  - CTMU temperature sensing

### **High-Performance CPU**

- High-Precision PLL for USB
- Two External Clock modes, Up to 64 MHz (16 MIPS<sup>®</sup>)
- Internal 31 kHz Oscillator
- High-Precision Internal Oscillator with Clock Recovery from SOSC to Achieve 0.15% Precision, 31 kHz to 8 MHz or 64 MHz w/PLL, ±0.15% Typical, ±1.5% Max.
- Secondary Oscillator using Timer1 @ 32 kHz
- C Compiler Optimized Instruction Set Architecture
- Two Address Generation Units for Separate Read and Write Addressing of Data Memory

## **Special Microcontroller Features**

- Operating Voltage Range of 2.0V to 3.6V
- Two On-Chip Voltage Regulators (1.8V and 1.2V) for Regular and Extreme Low-Power Operation
- 20,000 Erase/Write Cycle Endurance Flash Program Memory, Typical
- Flash Data Retention: 10 Years Minimum
- Self-Programmable under Software Control
- Two Configurable Reference Clock Outputs (REFO1 and REFO2)
- In-Circuit Serial Programming<sup>™</sup> (ICSP<sup>™</sup>)
- Fail-Safe Clock Monitor Operation:
- Detects clock failure and switches to on-chip, low-power RC oscillator

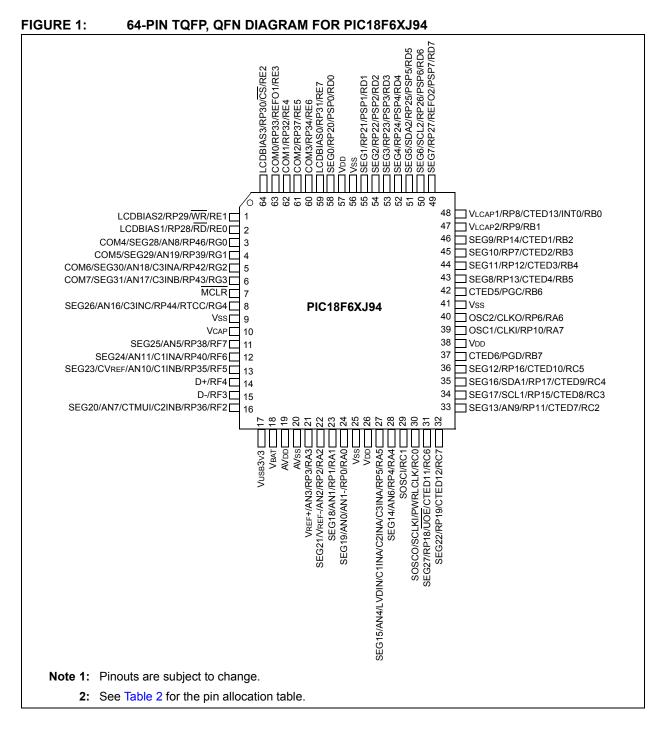

- Power-on Reset (POR), Power-up Timer (PWRT) and Oscillator Start-up Timer (OST)
- Brown-out Reset (BOR) with Operation Below VBOR, with Regulator Enabled
- High/Low-Voltage Detect (HLVD)
- Flexible Watchdog Timer (WDT) with its Own RC Oscillator for Reliable Operation
- Standard and Ultra Low-Power Watchdog Timers (WDT) for Reliable Operation in Standard and Deep Sleep modes

## TO OUR VALUED CUSTOMERS

It is our intention to provide our valued customers with the best documentation possible to ensure successful use of your Microchip products. To this end, we will continue to improve our publications to better suit your needs. Our publications will be refined and enhanced as new volumes and updates are introduced.

If you have any questions or comments regarding this publication, please contact the Marketing Communications Department via E-mail at **docerrors@microchip.com** or fax the **Reader Response Form** in the back of this data sheet to (480) 792-4150. We welcome your feedback.

#### **Most Current Data Sheet**

To obtain the most up-to-date version of this data sheet, please register at our Worldwide Website at:

#### http://www.microchip.com

You can determine the version of a data sheet by examining its literature number found on the bottom outside corner of any page. The last character of the literature number is the version number, (e.g., DS30000A is version A of document DS30000).

#### Errata

An errata sheet, describing minor operational differences from the data sheet and recommended workarounds, may exist for current devices. As device/documentation issues become known to us, we will publish an errata sheet. The errata will specify the revision of silicon and revision of document to which it applies.

To determine if an errata sheet exists for a particular device, please check with one of the following:

Microchip's Worldwide Website; http://www.microchip.com

Your local Microchip sales office (see last page)

When contacting a sales office, please specify which device, revision of silicon and data sheet (include literature number) you are using.

#### **Customer Notification System**

Register on our website at www.microchip.com to receive the most current information on all of our products.

#### 1.0 **DEVICE OVERVIEW**

This document contains device-specific information for the following devices:

- PIC18F97J94 PIC18F66J94
- PIC18F87J94
- PIC18F95J94
- PIC18F67J94
- PIC18F85J94
- PIC18F96J94
- PIC18F65J94
- PIC18F86J94

This family introduces a new line of low-voltage LCD microcontrollers with Universal Serial Bus (USB). It combines all the main traditional advantage of all PIC18 microcontrollers, namely, high computational performance and a rich feature set at an extremely competitive price point. These features make the PIC18F9XJ94 family a logical choice for many highperformance applications, where cost is a primary consideration.

#### 1.1 **Core Features**

#### 1.1.1 **TECHNOLOGY**

All of the devices in the PIC18F9XJ94 family incorporate a range of features that can significantly reduce power consumption during operation. Key items include:

- Alternate Run Modes: By clocking the controller from the Timer1 source or the Internal RC oscillator, power consumption during code execution can be reduced.
- Multiple Idle Modes: The controller can also run with its CPU core disabled but the peripherals still active. In these states, power consumption can be reduced even further.
- On-the-Fly Mode Switching: The power-managed modes are invoked by user code during operation, allowing the user to incorporate power-saving ideas into their application's software design.
- XLP: An extra low-power Sleep, BOR, RTCC and Watchdog Timer.

#### OSCILLATOR OPTIONS AND 1.1.2 **FEATURES**

All of the devices in the PIC18F9XJ94 family offer different oscillator options, allowing users a range of choices in developing application hardware. These include:

- Two Crystal modes (HS, MS)
- One External Clock mode (EC)
- · A Phase Lock Loop (PLL) frequency multiplier, which allows clock speeds of up to 64 MHz.
- A fast Internal Oscillator (FRC) block that provides an 8 MHz clock (±0.15% accuracy) with Active Clock Tuning (ACT) from USB or SOSC source.
  - Offers multiple divider options from 8 MHz to 500 kHz
  - Frees the two oscillator pins for use as additional general purpose I/O
- A separate Low-Power Internal RC Oscillator (LPRC) (31 kHz nominal) for low-power, timinginsensitive applications.

The internal oscillator block provides a stable reference source that gives the family additional features for robust operation:

- · Fail-Safe Clock Monitor (FSCM): This option constantly monitors the main clock source against a reference signal provided by the internal oscillator. If a clock failure occurs, the controller is switched to the internal oscillator, allowing for continued lowspeed operation or a safe application shutdown.
- Two-Speed Start-up (IESO): This option allows the internal oscillator to serve as the clock source from Power-on Reset, or wake-up from Sleep mode, until the primary clock source is available.

### 1.1.3 MEMORY OPTIONS

The PIC18F9XJ94 family provides ample room for application code, from 32 Kbytes to 128 Kbytes of code space. The Flash cells for program memory are rated to last up to 20,000 erase/write cycles. Data retention without refresh is conservatively estimated to be greater than 10 years.

The Flash program memory is readable and writable. During normal operation, the PIC18F9XJ94 family also provides plenty of room for dynamic application data with up to 3,578 bytes of data RAM.

#### 1.1.4 UNIVERSAL SERIAL BUS (USB)

Devices in the PIC18F9XJ94 family incorporate a fullyfeatured USB communications module with a built-in transceiver that is compliant with the USB Specification Revision 2.0. The module supports both low-speed and full-speed communication for all supported data transfer types.

#### 1.1.5 EXTERNAL MEMORY BUS

Should 128 Kbytes of memory be inadequate for an application, the 80-pin and 100-pin members of the PIC18F9XJ94 family have an External Memory Bus (EMB), enabling the controller's internal Program Counter to address a memory space of up to 2 Mbytes. This is a level of data access that few 8-bit devices can claim and enables:

- Using combinations of on-chip and external memory of up to 2 Mbytes
- Using external Flash memory for reprogrammable application code or large data tables
- Using external RAM devices for storing large amounts of variable data

### 1.1.6 EXTENDED INSTRUCTION SET

The PIC18F9XJ94 family implements the optional extension to the PIC18 instruction set, adding eight new instructions and an Indexed Addressing mode. Enabled as a device configuration option, the extension has been specifically designed to optimize re-entrant application code originally developed in high-level languages, such as 'C'.

#### 1.1.7 EASY MIGRATION

All devices share the same rich set of peripherals. This provides a smooth migration path within the device family as applications evolve and grow.

The consistent pinout scheme, used throughout the entire family, also aids in migrating to the next larger device. This is true when moving between the 64-pin members, between the 80-pin members, between the 100-pin members or even jumping from 64-pin to 80-pin to 100-pin devices.

The PIC18F9XJ94 family is also largely pin compatible with other PIC18 families, such as the PIC18F87J90, PIC18F87J11 and the PIC18F87J50. This allows a new dimension to the evolution of applications, allowing developers to select different price points within Microchip's PIC18 portfolio, while maintaining a similar feature set.

## 1.2 LCD Controller

The on-chip LCD driver includes many features that make the integration of displays in low-power applications easier. These include an integrated voltage regulator with charge pump and an integrated internal resistor ladder that allows contrast control in software and display operation above device VDD.

### 1.3 Other Special Features

- Communications: The PIC18F9XJ94 family incorporates a range of serial communication peripherals, including USB, four Enhanced Addressable USARTs with IrDA, and two Master Synchronous Serial Port MSSP modules capable of both SPI and I<sup>2</sup>C (Master and Slave) modes of operation.
- **CCP Modules:** PIC18F9XJ94 family devices incorporate up to seven Capture/Compare/PWM (CCP) modules. Up to six different time bases can be used to perform several different operations at once.
- ECCP Modules: The PIC18F9XJ94 family has three Enhanced CCP (ECCP) modules to maximize flexibility in control applications:
  - Up to eight different time bases for performing several different operations at once
  - Up to four PWM outputs for each module for a total of 12 PWMs
  - Other beneficial features, such as polarity selection, programmable dead time, auto-shutdown and restart, and Half-Bridge and Full-Bridge Output modes
- **12-Bit A/D Converter:** The PIC18F9XJ94 family has a software selectable, 10/12-bit Analog-to-Digital (A/D) Converter. It incorporates programmable acquisition time, allowing for a channel to be selected and a conversion to be initiated without waiting for a sampling period, and thus, reducing code overhead.
- Charge Time Measurement Unit (CTMU): The CTMU is a flexible analog module that provides accurate differential time measurement between pulse sources, as well as asynchronous pulse generation.
- Together with other on-chip analog modules, the CTMU can precisely measure time, measure capacitance or relative changes in capacitance, or generate output pulses that are independent of the system clock.
- LP Watchdog Timer (WDT): This enhanced version incorporates a 22-bit prescaler, allowing an extended time-out range that is stable across operating voltage and temperature. See Section 30.0 "Electrical Specifications" for time-out periods.
- Real-Time Clock and Calendar Module (RTCC): The RTCC module is intended for applications requiring that accurate time be maintained for extended periods of time, with minimum to no intervention from the CPU.
- The module is a 100-year clock and calendar with automatic leap year detection. The range of the clock is from 00:00:00 (midnight) on January 1, 2000 to 23:59:59 on December 31, 2099.

### 1.4 Details on Individual Family Members

Devices in the PIC18F9XJ94 family are available in 64pin, 80-pin and 100-pin packages. Block diagrams for the two groups are shown in Figure 1-1, Figure 1-2 and Figure 1-3.

The devices are differentiated from each other in these ways:

- Flash Program Memory:
  - PIC18FX5J94 32 Kbytes
  - PIC18FX6J94 64 Kbytes
  - PIC18FX7J94 128 Kbytes
- Data RAM:
  - All devices 4 Kbytes
- I/O Ports:
  - PIC18F6XJ9X (64-pin devices) seven bidirectional ports
  - PIC18F8XJ9X (80-pin devices) nine bidirectional ports
  - PIC18F9XJ9X (100-pin devices) eleven bidirectional ports
- A/D Channels:
  - PIC18F6XJXX (64-pin devices) 16 channels
  - PIC18F8XJXX (80-pin devices) 24 channels
  - PIC18F9XJXX (100-pin devices) 24 channels

All other features for devices in this family are identical. These are summarized in Table 1-1, Table 1-2 and Table 1-3.

The pinouts for all devices are listed in Table 1-4.

TABLE 1-1:	<b>DEVICE FEATURES FOR THE 64-PIN DEVICES</b>
------------	---

Features	PIC18F65J94 PIC18F66J94 PIC18F67J94

## 2.0 GUIDELINES FOR GETTING STARTED WITH PIC18FJ MICROCONTROLLERS

## 2.1 Basic Connection Requirements

Getting started with the PIC18FXXJ94 of 8-bit microcontrollers requires attention to a minimal set of device pin connection before proceeding with development.

The following pins must always be connected:

- All VDD and Vss pins
   (see Section 2.2 "Power Supply Pins")
- All AVDD and AVss pins, regardless of whether or not the analog device features are used (see Section 2.2 "Power Supply Pins")
- MCLR pin
   (see Section 2.3 "Master Clear (MCLR) Pin")

These pins must also be connected if they are being used in the end application:

- PGC/PGD pins used for In-Circuit Serial Programming<sup>™</sup> (ICSP<sup>™</sup>) and debugging purposes (see Section 2.5 "ICSP Pins")
- OSC1 and OSC2 pins when an external oscillator source is used
   (as Section 2.5 ("External Oscillator Bing"))

(see Section 2.6 "External Oscillator Pins")

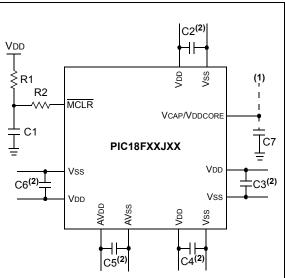

Additionally, the following pins may be required:

• VREF+/VREF- pins are used when external voltage reference for analog modules is implemented

**Note:** The AVDD and AVss pins must always be connected, regardless of whether any of the analog modules are being used.

The minimum mandatory connections are shown in Figure 2-1.

#### FIGURE 2-1: RECOMMENDED MINIMUM CONNECTIONS

#### Key (all values are recommendations):

C1 through C6: 0.1  $\mu$ F, 20V ceramic

C7: 10  $\mu\text{F},$  6.3V or greater, tantalum or ceramic R1: 10  $k\Omega$ 

R2: 100Ω to 470Ω

- Note 1: See Section 2.4 "Core Voltage Regulator (VCAP/VDDCORE)" for explanation of VCAP/ VDDCORE connections.
  - 2: The example shown is for a PIC18F device with five VDD/Vss and AVDD/AVss pairs. Other devices may have more or less pairs; adjust the number of decoupling capacitors appropriately.

## 2.2 Power Supply Pins

#### 2.2.1 DECOUPLING CAPACITORS

The use of decoupling capacitors on every pair of power supply pins, such as VDD, VSS, AVDD and AVSS, is required.

Consider the following criteria when using decoupling capacitors:

- Value and type of capacitor: A 0.1  $\mu$ F (100 nF), 10-20V capacitor is recommended. The capacitor should be a low-ESR device, with a resonance frequency in the range of 200 MHz and higher. Ceramic capacitors are recommended.
- Placement on the printed circuit board: The decoupling capacitors should be placed as close to the pins as possible. It is recommended to place the capacitors on the same side of the board as the device. If space is constricted, the capacitor can be placed on another layer on the PCB using a via; however, ensure that the trace length from the pin to the capacitor is no greater than 0.25 inch (6 mm).
- Handling high-frequency noise: If the board is experiencing high-frequency noise (upward of tens of MHz), add a second ceramic type capacitor in parallel to the above described decoupling capacitor. The value of the second capacitor can be in the range of 0.01  $\mu$ F to 0.001  $\mu$ F. Place this second capacitor next to each primary decoupling capacitor. In high-speed circuit designs, consider implementing a decade pair of capacitances as close to the power and ground pins as possible (e.g., 0.1  $\mu$ F in parallel with 0.001  $\mu$ F).
- Maximizing performance: On the board layout from the power supply circuit, run the power and return traces to the decoupling capacitors first, and then to the device pins. This ensures that the decoupling capacitors are first in the power chain. Equally important is to keep the trace length between the capacitor and the power pins to a minimum, thereby reducing PCB trace inductance.

#### 2.2.2 TANK CAPACITORS

On boards with power traces running longer than six inches in length, it is suggested to use a tank capacitor for integrated circuits, including microcontrollers, to supply a local power source. The value of the tank capacitor should be determined based on the trace resistance that connects the power supply source to the device, and the maximum current drawn by the device in the application. In other words, select the tank capacitor so that it meets the acceptable voltage sag at the device. Typical values range from 4.7  $\mu$ F to 47  $\mu$ F.

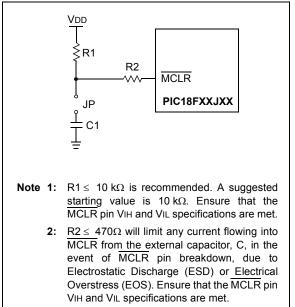

## 2.3 Master Clear (MCLR) Pin

The MCLR pin provides two specific device functions: Device Reset, and Device Programming and Debugging. If programming and debugging are not required in the end application, a direct connection to VDD may be all that is required. The addition of other components, to help increase the application's resistance to spurious Resets from voltage sags, may be beneficial. A typical configuration is shown in Figure 2-1. Other circuit designs may be implemented, depending on the application's requirements.

During programming and debugging, the resistance and capacitance that can be added to the pin must be considered. Device programmers and debuggers drive the MCLR pin. Consequently, specific voltage levels (VIH and VIL) and fast signal transitions must not be adversely affected. Therefore, specific values of R1 and C1 will need to be adjusted based on the application and PCB requirements. For example, it is recommended that the capacitor, C1, be isolated from the MCLR pin during programming and debugging operations by using a jumper (Figure 2-2). The jumper is replaced for normal run-time operations.

Any components associated with the  $\overline{\text{MCLR}}$  pin should be placed within 0.25 inch (6 mm) of the pin.

#### FIGURE 2-2: EXAMPLE OF MCLR PIN CONNECTIONS

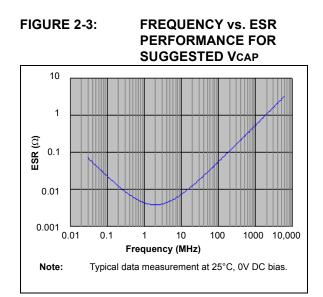

#### 2.4 Core Voltage Regulator (VCAP/ VDDCORE)

A low-ESR (< 5 $\Omega$ ) capacitor is required on the VCAP pin to stabilize the output voltage of the on-chip voltage regulator. The VCAP pin must not be connected to VDD and must use a capacitor of 10  $\mu$ F connected to ground. The type can be ceramic or tantalum. Suitable examples of capacitors are shown in Table 2-1. Capacitors with equivalent specification can be used.

Designers may use Figure 2-3 to evaluate ESR equivalence of candidate devices.

It is recommended that the trace length not exceed 0.25 inch (6 mm). Refer to **Section 30.0** "**Electrical Specifications**" for additional information.

Make	Part #	Nominal Capacitance	Base Tolerance	Rated Voltage	Temp. Range

## TABLE 2-1: SUITABLE CAPACITOR EQUIVALENTS

## 2.4.1 CONSIDERATIONS FOR CERAMIC CAPACITORS

In recent years, large value, low-voltage, surface-mount ceramic capacitors have become very cost effective in sizes up to a few tens of microfarad. The low-ESR, small physical size and other properties make ceramic capacitors very attractive in many types of applications.

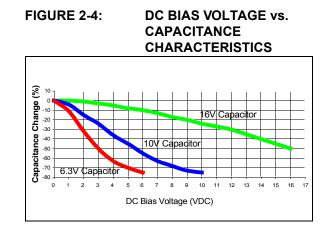

Ceramic capacitors are suitable for use with the VDDCORE voltage regulator of this microcontroller. However, some care is needed in selecting the capacitor to ensure that it maintains sufficient capacitance over the intended operating range of the application.

Typical low-cost, 10  $\mu$ F ceramic capacitors are available in X5R, X7R and Y5V dielectric ratings (other types are also available, but are less common). The initial tolerance specifications for these types of capacitors are often specified as ±10% to ±20% (X5R and X7R), or -20%/+80% (Y5V). However, the effective capacitance that these capacitors provide in an application circuit will also vary based on additional factors, such as the applied DC bias voltage and the temperature. The total in-circuit tolerance is, therefore, much wider than the initial tolerance specification.

The X5R and X7R capacitors typically exhibit satisfactory temperature stability (ex:  $\pm 15\%$  over a wide temperature range, but consult the manufacturer's data sheets for exact specifications). However, Y5V capacitors typically have extreme temperature tolerance specifications of  $\pm 22\%/-82\%$ . Due to the extreme temperature tolerance, a 10 µF nominal rated Y5V type capacitor may not deliver enough total capacitance to meet minimum VDDCORE voltage regulator stability and transient response requirements. Therefore, Y5V capacitors are not recommended for use with the VDDCORE regulator if the application must operate over a wide temperature range.

In addition to temperature tolerance, the effective capacitance of large value ceramic capacitors can vary substantially, based on the amount of DC voltage applied to the capacitor. This effect can be very significant, but is often overlooked or is not always documented.

A typical DC bias voltage vs. capacitance graph for X7R type and Y5V type capacitors is shown in Figure 2-4.

When selecting a ceramic capacitor to be used with the VDDCORE voltage regulator, it is suggested to select a high-voltage rating, so that the operating voltage is a small percentage of the maximum rated capacitor voltage. For example, choose a ceramic capacitor rated at 16V for the 2.5V VDDCORE voltage. Suggested capacitors are shown in Table 2-1.

## 2.5 ICSP Pins

The PGC and PGD pins are used for In-Circuit Serial Programming<sup>TM</sup> (ICSP<sup>TM</sup>) and debugging purposes. It is recommended to keep the trace length between the ICSP connector and the ICSP pins on the device as short as possible. If the ICSP connector is expected to experience an ESD event, a series resistor is recommended, with the value in the range of a few tens of ohms, not to exceed 100 $\Omega$ .

Pull-up resistors, series diodes, and capacitors on the PGC and PGD pins are not recommended as they will interfere with the programmer/debugger communications to the device. If such discrete components are an application requirement, they should be removed from the circuit during programming and debugging. Alternatively, refer to the AC/DC characteristics and timing requirements information in the respective device Flash programming specification for information on capacitive loading limits, and pin input voltage high (VIH) and input low (VIL) requirements.

For device emulation, ensure that the "Communication Channel Select" (i.e., PGCx/PGDx pins), programmed into the device, matches the physical connections for the ICSP to the Microchip debugger/emulator tool.

For more information on available Microchip development tools connection requirements, refer to **Section 31.0 "Development Support**".

## 2.6 External Oscillator Pins

Many microcontrollers have options for at least two oscillators: a high-frequency primary oscillator and a low-frequency secondary oscillator (refer to **Section 3.0 "Oscillator Configurations**" for details).

The oscillator circuit should be placed on the same side of the board as the device. Place the oscillator circuit close to the respective oscillator pins with no more than 0.5 inch (12 mm) between the circuit components and the pins. The load capacitors should be placed next to the oscillator itself, on the same side of the board.

Use a grounded copper pour around the oscillator circuit to isolate it from surrounding circuits. The grounded copper pour should be routed directly to the MCU ground. Do not run any signal traces or power traces inside the ground pour. Also, if using a two-sided board, avoid any traces on the other side of the board where the crystal is placed.

Layout suggestions are shown in Figure 2-5. In-line packages may be handled with a single-sided layout that completely encompasses the oscillator pins. With fine-pitch packages, it is not always possible to completely surround the pins and components. A suitable solution is to tie the broken guard sections to a mirrored ground layer. In all cases, the guard trace(s) must be returned to ground.

In planning the application's routing and I/O assignments, ensure that adjacent port pins, and other signals in close proximity to the oscillator, are benign (i.e., free of high frequencies, short rise and fall times, and other similar noise).

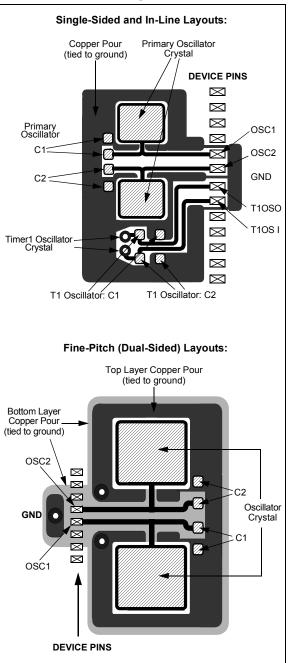

For additional information and design guidance on oscillator circuits, refer to these Microchip Application Notes, available at the corporate website (www.microchip.com):

- AN849, "Basic PICmicro<sup>®</sup> Oscillator Design"
- AN943, "Practical PICmicro<sup>®</sup> Oscillator Analysis and Design"
- AN949, "Making Your Oscillator Work"

## 2.7 Unused I/Os

Unused I/O pins should be configured as outputs and driven to a logic low state. Alternatively, connect a 1 k $\Omega$  to 10 k $\Omega$  resistor to Vss on unused pins and drive the output to logic low.

#### FIGURE 2-5: SUGGESTED PLACEMENT OF THE OSCILLATOR CIRCUIT

## 3.0 OSCILLATOR CONFIGURATIONS

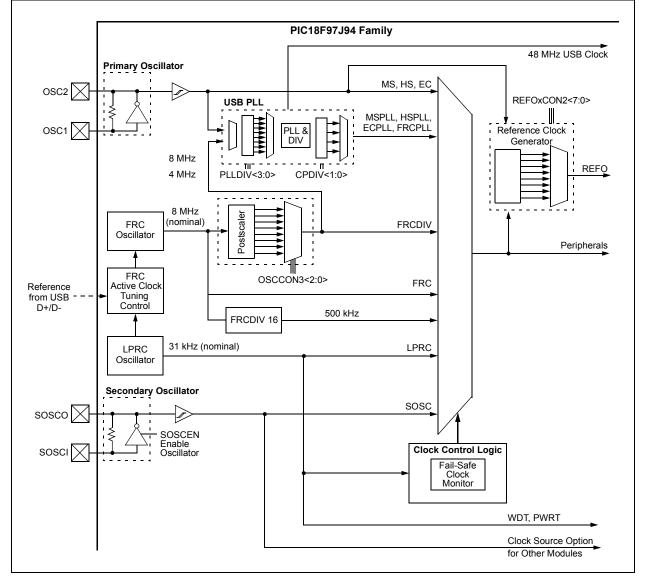

This section describes the PIC18F oscillator system and its operation. The PIC18F oscillator system has the following modules and features:

- A total of four external and internal oscillator options as clock sources, providing up to 11 different clock modes
- An on-chip USB PLL block to provide a stable 48 MHz clock for the USB module, as well as a range of frequency options for the system clock

- Software-controllable switching between various clock sources
- Software-controllable postscaler for selective clocking of CPU for system power savings
- A Fail-Safe Clock Monitor (FSCM) that detects clock failure and permits safe application recovery or shutdown
- A separate and independently configurable system clock output for synchronizing external hardware

A simplified diagram of the oscillator system is shown in Figure 3-1.

## 3.1 CPU Clocking Scheme

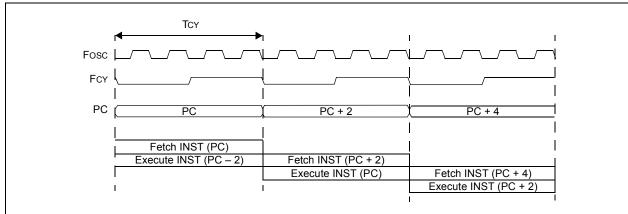

The system clock source can be provided by one of four sources:

- Primary Oscillator (POSC) on the OSC1 and OSC2 pins
- Secondary Oscillator (SOSC) on the SOSCI and SOSCO pins
- · Fast Internal RC (FRC) Oscillator
- · Low-Power Internal RC (LPRC) Oscillator

The Primary Oscillator and FRC sources have the option of using the internal USB PLL block, which generates both the USB module clock and a separate system clock from the 96 MHz PLL. Refer to **Section 3.8.1 "Oscillator Modes and USB Operation"** for additional information.

The internal FRC provides an 8 MHz clock source. It can optionally be reduced by the programmable clock divider to provide a range of system clock frequencies.

The selected clock source generates the processor and peripheral clock sources. The processor clock source is divided by four to produce the internal instruction cycle clock, FCY. In this document, the instruction cycle clock is also denoted by FOSC/4. The internal instruction cycle clock, FOSC/4, can be provided on the OSC2 I/O pin for some operating modes of the Primary Oscillator. The timing diagram in Figure 3-2 shows the relationship between the processor clock source and instruction execution.

## FIGURE 3-2: CLOCK OR INSTRUCTION CYCLE TIMING

## 3.2 Oscillator Configuration

The oscillator source (and operating mode) that is used at a device Power-on Reset (POR) event is selected using Configuration bit settings. The Oscillator Configuration bit settings are in the Configuration registers located in the program memory (refer to **Section 28.1 "Configuration Bits"** for more information). The Primary Oscillator Configuration bits, POSCMD<1:0> (CONFIG3L<1:0>), and Oscillator Configuration bits, FOSC<2:0> (CONFIG2L<2:0>), select the oscillator source that is used at a POR. The FRC Oscillator with Postscaler (FRCDIV) is the default (unprogrammed) selection. The Secondary Oscillator, or one of the internal oscillators, may be chosen by programming these bit locations.

The Configuration bits allow users to choose between 11 different clock modes, as shown in Table 3-1.

<b>TABLE 3-1</b> :	CONFIGURATION BIT VALUES FOR CLOCK SELECTION
--------------------	--

Oscillator Mode	<b>Oscillator Source</b>	POSCMD<1:0>	FOSC<2:0>	Notes
Fast RC Oscillator with Postscaler (FRCDIV)	Internal	11	111	1, 2
Fast RC Oscillator divided by 16 (FRC500kHz)	Internal	11	110	1
Low-Power RC Oscillator (LPRC)	Internal	11	101	1
Secondary (Timer1) Oscillator (SOSC)	Secondary	11	100	1
Primary Oscillator (HS) with PLL Module (HSPLL)	Primary	10	011	
Primary Oscillator (MS) with PLL Module (MSPLL)	Primary	01	011	
Primary Oscillator (EC) with PLL Module (ECPLL)	Primary	00	011	
Primary Oscillator (HS)	Primary	10	010	
Primary Oscillator (MS)	Primary	01	010	
Primary Oscillator (EC)	Primary	00	010	
Fast RC Oscillator with PLL Module (FRCPLL)	Internal	11	001	1
Fast RC Oscillator (FRC)	Internal	11	000	1

**Note 1:** OSC2 pin function is determined by the CLKOEN Configuration bit.

**2:** Default oscillator mode for an unprogrammed (erased) device.

## 3.2.1 CLOCK SWITCHING MODE CONFIGURATION BITS

The FSCMx Configuration bits (CONFIG3L<5:4>) are used to jointly configure device clock switching and the Fail-Safe Clock Monitor (FSCM). Clock switching is enabled only when FSCM1 is programmed ('0'). The FSCM is enabled only when FSCM<1:0> are both programmed ('00').

#### 3.2.2 OSC1 AND OSC2 PIN FUNCTIONS IN NON-CRYSTAL MODES

When the Primary Oscillator on OSC1 and OSC2 is not configured as the clock source (POSCMD<1:0> = 11), the OSC1 pin is automatically reconfigured as a digital I/O. In this configuration, as well as when the Primary Oscillator is configured for EC mode (POSCMD<1:0> = 00), the OSC2 pin can also be configured as a digital I/O by programming the CLKOEN Configuration bit (CONFIG2L<5>).

When CLKOEN is unprogrammed ('1'), a Fosc/4 clock output is available on OSC2 for testing or synchronization purposes. With CLKOEN programmed ('0'), the OSC2 pin becomes a general purpose I/O pin. In both of these configurations, the feedback device between OSC1 and OSC2 is turned off to save current.

## 3.3 Control Registers

The operation of the oscillator is controlled by six Special Function Registers (SFRs):

- OSCCON
- OSCCON2
- OSCCON3
- OSCCON4
- ACTCON
- OSCTUNE

#### 3.3.1 OSCILLATOR CONTROL REGISTER (OSCCON)

The OSCCON register (Register 3-1) is the main control register for the oscillator. It controls clock source switching and allows the monitoring of clock sources.

The COSCx (OSCCON<6:4>) Status bits are read-only bits that indicate the current oscillator source the device is operating from. The COSCx bits default to the Internal Fast RC Oscillator with Postscaler (FRCDIV), configured for 4 MHz, on a Power-on Reset (POR) and Master Clear Reset (MCLR). A clock switch will automatically be performed to the new oscillator source selected by the FOSCx Configuration bits (CON-FIG2L<2:0>). The COSCx bits will change to indicate the new oscillator source at the end of a clock switch operation.

The NOSCx Status bits select the clock source for the next clock switch operation. On POR and MCLRs, these bits automatically select the oscillator source defined by the FOSCx Configuration bits. These bits can be modified by software.

Setting the CLKLOCK bit (OSCCON2<7>) prevents clock switching if the FSCM1 Configuration bit is set. If the FSCM1 bit is clear, the CLKLOCK bit state is ignored and clock switching can occur.

The IOLOCK bit (OSCCON2<6>) is used to unlock the Peripheral Pin Select (PPS) feature; it has no function in the system clock's operation.

The LOCK Status bit (OSCCON2<5>) is read-only and indicates the status of the PLL circuit. It is set when the PLL achieves a frequency lock and is reset when a valid clock switching sequence is initiated. It reads as '0' whenever the PLL is not used as part of the current clock source.

The CF Status bit (OSCCON2<3>) is a readable/clearable Status bit that indicates a clock failure; it is reset whenever a valid clock switch occurs.

The POSCEN bit (OSCCON2<2>) is used to control the operation of the Primary Oscillator in Sleep mode. Setting this bit bypasses the normal automatic shutdown of the oscillator whenever Sleep mode is invoked.

The Secondary Oscillator can be turned on by a variety of options:

- SOSCGO OSCCON2<1>
- SOSCSEL CONFIG2L<3>
- FOSC<2:0> CONFIG2L<2:0>
- DSWDTOSC CONFIG8H<1>
- RTCEN RTCCON1<7>
- SOSCEN T1CON<3>, T3CON<3> or T5CON<3>

The ACTCON register (Register 3-10) controls the Active Clock Tuning features.

#### 3.3.2 OSCCON3 – CLOCK DIVIDER REGISTER (IRCF<2:0> BITS)

The IRCFx bits (OSCCON3<2:0>) select the postscaler option for the FRC Oscillator output, allowing users to choose a lower clock frequency than the nominal 8 MHz.

This option is described in more detail in Section 3.10.2 "FRC Postscaler Mode (FRCDIV)" and Section 3.10.3 "FRC Oscillator with PLL Mode (FRCPLL)".

#### 3.3.3 OSCILLATOR TUNING REGISTER (OSCTUNE)

The FRC Oscillator Tuning register (Register 3-5) allows the user to fine-tune the FRC Oscillator. Refer to the data sheet of the specific device for further information regarding the FRC Oscillator tuning.

The tuning response of the FRC Oscillator may not be monotonic or linear; the next closest frequency may be offset by a number of steps. It is recommended that users try multiple values of OSCTUNE to find the closest value to the desired frequency.

#### 3.4 Reference Clock Output Control Module

The PIC18F97J94 family has two Reference Clock Output (REFO) modules. Each of the Reference Clock Output modules provides the user with the ability to send out a programmed output clock onto the REFO1or REFO2 pins.

#### 3.4.1 REFERENCE CLOCK SOURCE

The module provides the ability to select one of the following clock sources:

- Primary Crystal Oscillator (POSC)
- Secondary Crystal Oscillator (SOSC)
- 32.768 kHz Internal Oscillator (INTOSC)
- Fast Internal Oscillator (FRC)

It includes a programmable clock divider with ratios ranging from 1:1 to 1:65534.

When the clock source is a crystal or internal oscillator, the RSLP bit can be set to continue REFO operation while the device is in Sleep Mode.

#### 3.4.2 CLOCK SYNCHRONIZATION

The Reference Clock Output is enabled only once (ON = 1). Note that the source of the clock and the divider values should be chosen prior to the bit being set to avoid glitches on the REFO output.

Once the ON bit is set, its value is synchronized to the Reference Clock Output domain to enable the output. This ensures that no glitches will be seen on the output. Similarly, when the ON bit is cleared, the output and the associated output enable signals will be synchronized and disabled on the falling edge of the Reference Clock Output. Note that with large divider values, this will cause the REFO to be enabled for some period after ON is cleared.

#### 3.4.3 OPERATION IN SLEEP MODE

If any clock source, other than the peripheral clock, is used as a base reference (i.e.,  $ROSEL<3:0> \neq 0001$ ), the user has the option to configure the behavior of the oscillator in Sleep mode. The RSLP Configuration bit determines if the oscillator will continue to run in Sleep. If RSLP = 0, the oscillator will be shut down in Sleep (assuming no other consumers are requesting it). If RSLP = 1, the oscillator will continue to run in Sleep.

The Reference Clock Output is synchronized with the Sleep signal to avoid any glitches on its output.

#### 3.4.3.1 Module Enable Signal

The REFOx module may be enabled or disabled using the REFOxMD register bit, which holds the REFOx module in Reset, or the ON register bit, which does not.

#### 3.4.3.2 Registers and Bits

This module provides the following device registers and/or bits:

- REFOxCON Reference Clock Output Control Register
- REFOxCON1 Reference Clock Output Control 1 Register
- REFOxCON2 Reference Clock Output Control 2 Register
- REFOxCON3 Reference Clock Output Control 3 Register

In addition, the REFOxCON1 module needs to be enabled by clearing the REFOxMD disable bit (PMD3<1>).

#### 3.4.3.3 Interrupts

This module does not generate any interrupts.

**Note:** Throughout this section, references to register and bit names that may be associated with specific Reference Clock Output modules are referred to generically by the use of 'x' in place of the specific module number. Thus, "REFOxCON" might refer to the control register for either REFO1 or REFO2.

## 3.5 Primary Oscillator (POSC)

The Primary Oscillator is available on the OSC1 and OSC2 pins of the PIC18F family. In general, the Primary Oscillator can be configured for an external clock

input or an external crystal. Further details of the Primary Oscillator operating modes are described in subsequent sections. The Primary Oscillator has up to 6 operating modes, summarized in Table 3-2.

Oscillator Mode	Description	OSC2 Pin Function
EC	External clock input (0-64 MHz)	Fosc/4
ECPLL	External clock input (4-48 MHz), PLL enabled	Fosc/4, Note 2
HS	10 MHz-32 MHz crystal	Note 1
HSPLL	10 MHz-32 MHz crystal, PLL enabled	Note 2
MS	3.5 MHz-10 MHz crystal	Note 1
MSPLL	3.5 MHz-8 MHz crystal, PLL enabled	Note 1

TABLE 3-2:	PRIMARY OSCILLATOR OPERATING MODES	

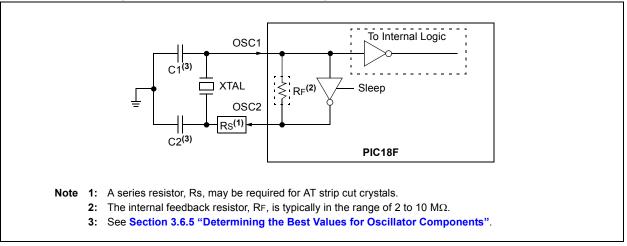

Note 1: External crystal is connected to OSC1 and OSC2 in these modes.

2: Available only in devices with special PLL blocks (such as the 96 MHz PLL); the basic 4x PLL block generates clock frequencies beyond the device's operating range.

The POSCMDx and FOSCx Configuration bits (CON-FIG3L<1:0> and CONFIG2L<2:0>, respectively) select the operating mode of the Primary Oscillator. The POSCMD<1:0> bits select the particular submode to be used (MS, HS or EC), while the FOSC<2:0> bits determine if the oscillator will be used by itself or with the internal PLL. The PIC18F operates from the Primary Oscillator whenever the COSCx bits (OSCCON<6:4>) are set to '010' or '011'.

Refer to the "**Electrical Characteristics**" section in the specific device data sheet for further information regarding frequency range for each crystal mode.

## FIGURE 3-3: CRYSTAL OR CERAMIC RESONATOR OPERATION (MS OR HS OSCILLATOR MODE)

#### 3.5.1 SELECTING A PRIMARY OSCILLATOR MODE

The main difference between the MS and HS modes is the gain of the internal inverter of the oscillator circuit, which allows the different frequency ranges. The MS mode is a medium power, medium frequency mode. HS mode provides the highest oscillator frequencies with a crystal. OSC2 provides crystal feedback in both HS and MS Oscillator modes.

The EC and HS modes that use the PLL circuit provide the highest device operating frequencies. The oscillator circuit will consume the most current in these modes because the PLL is enabled to multiply the frequency of the oscillator.

In general, users should select the oscillator option with the lowest possible gain that still meets their specifications. This will result in lower dynamic currents (IDD). The frequency range of each oscillator mode is the recommended frequency cutoff, but the selection of a different gain mode is acceptable as long as a thorough validation is performed (voltage, temperature and component variations, such as resistor, capacitor and internal oscillator circuitry).

The oscillator feedback circuit is disabled in all EC modes. The OSC1 pin is a high-impedance input and can be driven by a CMOS driver.

If the Primary Oscillator is configured for an external clock input, the OSC2 pin is not required to support the oscillator function. For these modes, the OSC2 pin can be used as an additional device I/O pin or a clock output pin. When the OSC2 pin is used as a clock output pin, the output frequency is Fosc/4.

## 3.6 Crystal Oscillators and Ceramic Resonators

In MS and HS modes, a crystal or ceramic resonator is connected to the OSC1 and OSC2 pins to establish oscillation (Figure 3-3). The PIC18F oscillator design requires the use of a parallel cut crystal. Using a series cut crystal may give a frequency out of the crystal manufacturer's specifications.

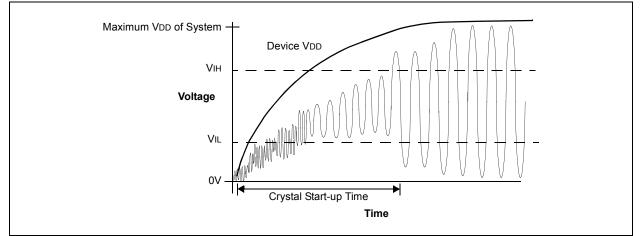

#### 3.6.1 OSCILLATOR/RESONATOR START-UP

As the device voltage increases from Vss, the oscillator will start its oscillations. The time required for the oscillator to start oscillating depends on many factors, including:

- Crystal/resonator frequency
- · Capacitor values used
- · Series resistor, if used, and its value and type
- · Device VDD rise time
- System temperature
- Oscillator mode selection of device (selects the gain of the internal oscillator inverter)
- · Crystal quality
- Oscillator circuit layout
- System noise

The course of a typical crystal or resonator start-up is shown in Figure 3-4. Notice that the time to achieve stable oscillation is not instantaneous.

#### FIGURE 3-4: EXAMPLE OSCILLATOR/RESONATOR START-UP CHARACTERISTICS

#### 3.6.2 PRIMARY OSCILLATOR START-UP FROM SLEEP MODE

The most difficult time for the oscillator to start-up is when waking up from Sleep mode. This is because the load capacitors have both partially charged to some quiescent value and phase differential at wake-up is minimal. Thus, more time is required to achieve stable oscillation. Also remember that low voltage, high temperatures and the lower frequency clock modes also impose limitations on loop gain, which in turn, affects start-up.

Each of the following factors increases the start-up time:

- Low-frequency design (with a Low Gain Clock mode)
- Quiet environment (such as a battery-operated device)
- Operating in a shielded box (away from the noisy RF area)
- · Low voltage
- High temperature
- Wake-up from Sleep mode

Circuit noise, on the other hand, may actually help to "kick start" the oscillator and help to lower the oscillator start-up time.

#### 3.6.3 OSCILLATOR START-UP TIMER

In order to ensure that a crystal oscillator (or ceramic resonator) has started and stabilized, an Oscillator Start-up Timer (OST) is provided. The OST is a simple, 10-bit counter that counts 1024 Tosc cycles before releasing the oscillator clock to the rest of the system. This time-out period is designated as TOST. The amplitude of the oscillator signal must reach the VIL and VIH thresholds for the oscillator pins before the OST can begin to count cycles.

The TOST interval is required every time the oscillator has to restart (i.e., on POR, BOR and wake-up from Sleep mode). The Oscillator Start-up Timer is applied to the MS and HS modes for the Primary Oscillator, as well as the Secondary Oscillator, SOSC (see Section 3.9 "Secondary Oscillator (SOSC)").

#### 3.6.4 TUNING THE OSCILLATOR CIRCUIT

Since Microchip devices have wide operating ranges (frequency, voltage and temperature, depending on the part and version ordered), and external components (crystals, capacitors, etc.) of varying quality and manufacture, validation of operation needs to be performed to ensure that the component selection will comply with the requirements of the application. There are many factors that go into the selection and arrangement of these external components. Depending on the application, these may include any of the following:

- Amplifier gain
- Desired frequency
- · Resonant frequency(s) of the crystal
- · Temperature of operation
- Supply voltage range
- · Start-up time
- Stability
- Crystal life
- Power consumption
- · Simplification of the circuit
- · Use of standard components
- Component count

#### 3.6.5 DETERMINING THE BEST VALUES FOR OSCILLATOR COMPONENTS

The best method for selecting components is to apply a little knowledge, and a lot of trial measurement and testing. Crystals are usually selected by their parallel resonant frequency only; however, other parameters may be important to your design, such as temperature or frequency tolerance. Microchip Application Note *AN588, "PICmicro<sup>®</sup> Microcontroller Oscillator Design Guide"* (DS0000588) is an excellent reference to learn more about crystal operation and ordering information.

The PIC18F internal oscillator circuit is a parallel oscillator circuit which requires that a parallel resonant crystal be selected. The load capacitance is usually specified in the 22 pF to 33 pF range. The crystal will oscillate closest to the desired frequency, with a load capacitance in this range. It may be necessary to alter these values, as described later, in order to achieve other benefits.

The clock mode is primarily chosen based on the desired frequency of the crystal oscillator. The main difference between the MS and HS Oscillator modes is the gain of the internal inverter of the oscillator circuit, which allows the different frequency ranges. In general, use the oscillator option with the lowest possible gain that still meets specifications. This will result in lower dynamic currents (IDD). The frequency range of each oscillator mode is the recommended frequency cutoff, but the selection of a different gain mode is acceptable as long as a thorough validation is performed (voltage, temperature and component variations, such as resistor, capacitor and internal oscillator circuitry). C1 and C2 should also be initially selected based on the load capacitance, as suggested by the crystal manufacturer, and the tables supplied in the device data sheet. The values given in the device data sheet can only be used as a starting point, since the crystal manufacturer, supply voltage, and other factors already mentioned, may cause your circuit to differ from the one used in the factory characterization process.

Ideally, the capacitance is chosen so that it will oscillate at the highest temperature and the lowest VDD that the circuit will be expected to perform under. High temperature and low VDD both have a limiting effect on the loop gain, such that if the circuit functions at these extremes, the designer can be more assured of proper operation at other temperatures and supply voltage combinations. The output sine wave should not be clipped in the highest gain environment (highest VDD and lowest temperature) and the sine output amplitude should be large enough in the lowest gain environment (lowest VDD and highest temperature) to cover the logic input requirements of the clock, as listed in the device data sheet. OSC1 may have specified VIL and VIH levels (refer to the specific product data sheet for more information).

A method for improving start-up is to use a value of C2 greater than C1. This causes a greater phase shift across the crystal at power-up, which speeds oscillator start-up. Besides loading the crystal for proper frequency response, these capacitors can have the effect of lower-ing loop gain if their value is increased. C2 can be selected to affect the overall gain of the circuit. A higher C2 can lower the gain if the crystal is being overdriven (also see discussion on Rs). Capacitance values that are too high can store and dump too much current through the crystal, so C1 and C2 should not become excessively large. Unfortunately, measuring the wattage through a crystal is difficult, but if you do not stray too far from the suggested values, you should not have to be concerned with this.

A series resistor, Rs, is added to the circuit if after all other external components are selected to satisfaction, and the crystal is still being overdriven. This can be determined by looking at the OSC2 pin, which is the driven pin, with an oscilloscope. Connecting the probe to the OSC1 pin will load the pin too much and negatively affect performance. Remember that a scope probe adds its own capacitance to the circuit, so this may have to be accounted for in your design (i.e., if the circuit worked best with a C2 of 22 pF and the scope probe was 10 pF, a 33 pF capacitor may actually be called for). The output signal should not be clipping or flattened. Overdriving the crystal can also lead to the circuit jumping to a higher harmonic level, or even, crystal damage.

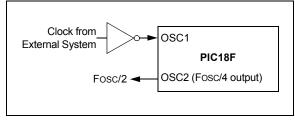

The OSC2 signal should be a clean sine wave that easily spans the input minimum and maximum of the clock input pin. An easy way to set this is to again test the circuit at the minimum temperature and maximum VDD that the design will be expected to perform in; then, look at the output. This should be the maximum amplitude of the clock output. If there is clipping, or the sine wave is distorted near VDD and VSS, increasing load capacitors may cause too much current to flow through the crystal, or push the value too far from the manufacturer's load specification. To adjust the crystal current, add a trimmer potentiometer between the crystal inverter output pin and C2, and adjust it until the sine wave is clean. The crystal will experience the highest drive currents at the low temperature and high VDD extremes.

The trimmer potentiometer should be adjusted at these limits to prevent overdriving. A series resistor, Rs, of the closest standard value can now be inserted in place of the trimmer. If Rs is too high, perhaps more than 20 k $\Omega$ , the input will be too isolated from the output, making the clock more susceptible to noise. If you find a value this high is needed to prevent overdriving the crystal, try increasing C2 to compensate or changing the oscillator operating mode. Try to get a combination where Rs is around 10 k $\Omega$  or less, and load capacitance is not too far from the manufacturer's specification.

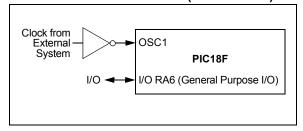

## 3.7 External Clock Input

In EC mode, the OSC1 pin is in a high-impedance state and can be driven by CMOS drivers. The OSC2 pin can be configured as either an I/O or the clock output (Fosc 4) by selecting the CLKOEN bit (CONFIG2L<5>). With CLKOEN set (Figure 3-5), the clock output is available for testing or synchronization purposes. With CLKOEN clear (Figure 3-6), the OSC2 pin becomes a general purpose I/O pin. The feedback device between OSC1 and OSC2 is turned off to save current.

#### FIGURE 3-5: EXTERNAL CLOCK INPUT OPERATION (CLKOEN = 1)

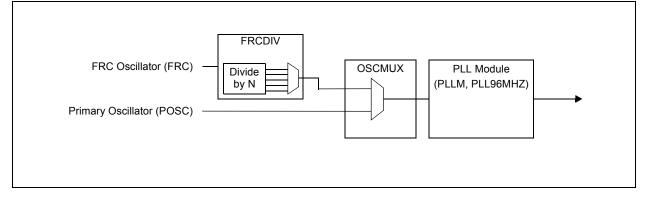

#### FIGURE 3-6: EXTERNAL CLOCK INPUT OPERATION (CLKOEN = 0)

### 3.8 Phase Lock Loop (PLL) Branch

The PLL module contains two separate PLL submodules: PLLM and PLL96MHZ. The PLLM submodule is configurable as a 4x, 6x or 8x PLL. The PLL96MHZ submodule runs at 96 MHz and requires an input clock between 4 MHz and 48 MHz (a multiple of 4 MHz). These are selected through the PLLDIV<3:0> bits.

#### FIGURE 3-7: BASIC OSCILLATOR BLOCK DIAGRAM

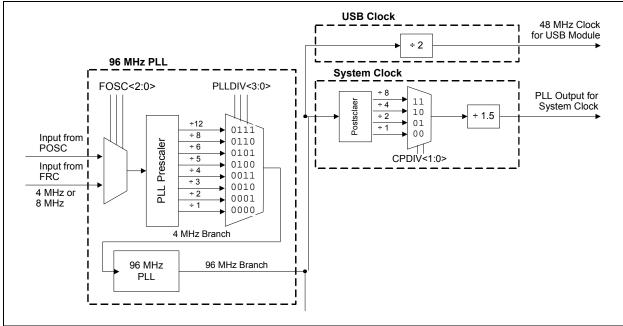

#### 3.8.1 OSCILLATOR MODES AND USB OPERATION

Because of the timing requirements imposed by USB, an internal clock of 48 MHz is required at all times while the USB module is enabled and not in a suspended operating state. A method is provided to internally generate both the USB and system clocks from a single oscillator source. PIC18F97J94 family devices use the same clock structure as most other PIC18 devices, but include a two-branch PLL system to generate the two clock signals.

The USB PLL block is shown in Figure 3-8. In this system, the input from the Primary Oscillator is divided down by a PLL prescaler to generate a 4 MHz output.

This is used to drive an on-chip 96 MHz PLL frequency multiplier to drive the two clock branches. One branch uses a fixed, divide-by-2 frequency divider to generate the 48 MHz USB clock. The other branch uses a fixed, divide-by-1.5 frequency divider and configurable PLL prescaler/divider to generate a range of system clock frequencies. The CPDIVx bits select the system clock speed; available clock options are listed in Table 3-3.

The USB PLL prescaler does not automatically sense the incoming oscillator frequency. The user must manually configure the PLL divider to generate the required 4 MHz output, using the PLLDIV<3:0> Configuration bits. This limits the choices for Primary Oscillator frequency to a total of 8 possibilities, shown in Table 3-4.

#### FIGURE 3-8: 96 MHz PLL BLOCK

## TABLE 3-3:SYSTEM CLOCK OPTIONS<br/>DURING USB OPERATION

MCU Clock Division (CPDIV<1:0>)	System Clock Frequency (Instruction Rate in MIPS <sup>®</sup> )
None (00)	64 MHz (16)
÷2(01)	32 MHz (8)
÷4 (10)	16 MHz (4)
÷8 (11)	8 MHz (2) <sup>(1)</sup>

Note 1: These options are not compatible with USB operation. They may be used whenever the PLL branch is selected and the USB module is disabled.

#### TABLE 3-4: VALID PRIMARY OSCILLATOR CONFIGURATIONS FOR USB OPERATIONS

Input Oscillator Frequency	Clock Mode	PLL Division (PLLDIV<2:0>)
48 MHz	ECPLL	÷ <b>12 (</b> 111)
32 MHz	ECPLL	÷8(110)
24 MHz	HSPLL, ECPLL	÷6 (101)
20 MHz	HSPLL, ECPLL	÷5 (100)
16 MHz	HSPLL, ECPLL	÷4 (011)
12 MHz	HSPLL, ECPLL	÷3 (010)
8 MHz	ECPLL, MSPLL, FRCPLL <sup>(1)</sup>	÷2(001)
4 MHz	ECPLL, MSPLL, FRCPLL <sup>(1)</sup>	÷1 (000)

**Note 1:** FRCPLL with ±0.25% accuracy can be used for USB operation.

Note:	Because of USB clocking accuracy requirements (±0.25%), not all PIC18F devices support the use of the FRCPLL system clock configuration for USB operation. Refer to the specific device data sheet for details on the FRC Oscillator
	module.

# 3.8.2 CONSIDERATIONS FOR USING THE PLL BLOCK

All PLL blocks use the LOCK bit (OSCCON2<5>) as a read-only Status bit to indicate the lock status of the PLL. It is automatically set after the typical time delay for the PLL to achieve lock, designated as TLOCK. It is cleared at a POR and on clock switches when the PLL is selected as a clock source. It remains clear when any clock source not using the PLL is selected.

If the PLL does not stabilize properly during start-up, the LOCK bit may not reflect the actual status of the PLL lock, nor does it detect when the PLL loses lock during normal operation. Refer to the "**Electrical Characteristics**" section in the specific device data sheet for further information on the PLL lock interval.

Using any PLL block with the FRC Oscillator provides a stable system clock for microcontroller operations. USB operation is only possible with FRC Oscillators that are implemented with ±1/4% frequency accuracy. Serial communications using USART are only possible when FRC Oscillators are implemented with ±2% frequency accuracy. The PIC18F97J94 family is able to meet the required oscillator accuracy for both USB and USART providing stable communication by use of its active clock tuning feature. Refer to Section 3.13.3 "Active Clock Tuning (ACT) Module" for more information.

If an application is being migrated between PIC18F platforms with different PLL blocks, the differences in PLL and clock options may require the reconfiguration of peripherals that use the system clock. This is particularly true with serial communication peripherals, such as the USARTs.

## 3.9 Secondary Oscillator (SOSC)

In most PIC18F devices, the low-power Secondary Oscillator (SOSC) is implemented to run with a 32.768 kHz crystal. The oscillator is located on the SOSCO and SOSCI device pins, and serves as a secondary crystal clock source for low-power operation. It is used to drive Timer1, Real-Time Clock and Calendar (RTCC) and other modules requiring a clock signal while in low-power operation.

#### 3.9.1 ENABLING THE SECONDARY OSCILLATOR

The operation of the SOSC is selected by the FOSCx Configuration bits or by selection of the NOSCx bits (OSCCON<2:0>). The SOSC can also be enabled by setting the SOSCEN bit in Timer1, Timer3 or Timer5. The SOSC has a long start-up time; therefore, to avoid delays for peripheral start-up, the SOSC can be manually started using one of the SOSCEN bits.

#### 3.9.2 SECONDARY OSCILLATOR OPERATION

#### 3.9.2.1 Continuous Operation

The SOSC is always running when any of the SOSCEN bits are set. Leaving the oscillator running at all times allows a fast switch to the 32 kHz system clock for lower power operation. Returning to the faster main oscillator still requires an oscillator start-up time if it is a crystal-type source. This start-up time can be avoided on PLL clock sources by setting the PLLEN bit (OSC-CON4<5>) in advance of switching the clock source.

In addition, the oscillator will need to remain running at all times for Real-Time Clock (RTC) application using Timer1 or the RTCC module. Refer to **Section 14. "Timers"** and **Section 29. "Real-Time Clock and Calendar (RTCC)"** in the *"PIC18F Family Reference Manual"* for further details.

#### 3.9.2.2 Intermittent Operation

When all SOSCEN bits are cleared, the oscillator will only operate when it is selected as the current device clock source (COSC<2:0> = 100). It will be disabled automatically if it is the current device clock source and the device enters Sleep mode.

#### 3.9.3 OPERATING MODES

#### 3.9.3.1 Digital Mode

The SOSCO pin can also be configured to operate as a digital clock input. The SOSCO pin is configured as a digital input by setting SOSCSEL (CONFIG2L<3>) = 10.

When running in this mode, the SOSCO/SCLKI pin will operate as a digital input to the oscillator section, while the SOSCI pin will function as a port pin. The crystal driving circuit is disabled. The Oscillator Configuration Fuse bits (FOSC<2:0>) and New Oscillator Selection bits (NOSC<2:0>) have no effect.

#### 3.9.4 SOSC CRYSTAL SELECTION

A typical 50K ESR and 12.5 pF CL (capacitive loading) rated crystal is recommended for reliable operation of the SOSC. The duty cycle of the SOSC output can be measured on the REFO pin, and is recommended to be within +/-15% from a 50% duty cycle.

## 3.10 Internal Fast RC Oscillator (FRC)

The FRC Oscillator is a fast (8 MHz nominal), internal RC Oscillator. This oscillator is intended to be a precise internal RC Oscillator accurate enough to provide the clock frequency necessary to maintain baud rate tolerance for serial data transmissions, without the use of an external crystal or ceramic resonator. The PIC18F device operates from the FRC Oscillator whenever the COSCx bits are '111', '110', '001' or '000'.

#### 3.10.1 ENABLING THE FRC OSCILLATOR

Since it serves as the system clock during device initialization, the FRC Oscillator is always enabled at a POR. After the device is configured and PWRT expires, FRC remains active only if it is selected as the device clock source.

#### 3.10.2 FRC POSTSCALER MODE (FRCDIV)

Users are not limited to the nominal 8 MHz FRC output if they wish to use the Fast Internal Oscillator as a clock source. An additional FRC mode, FRCDIV, implements a selectable postscaler that allows the choice of a lower clock frequency, from 7 different options, plus the direct 8 MHz output. The postscaler is configured using the IRCF<2:0> bits (OSCCON3<2:0>). Assuming a nominal 8 MHz output, available lower frequency options range from 4 MHz (divide-by-2) to 31 kHz (divide-by-256). The range of frequencies allows users the ability to save power at any time in an application by simply changing the IRCFx bits.

The FRCDIV mode is selected whenever the COSCx bits are '111'.

## 3.10.3 FRC OSCILLATOR WITH PLL MODE (FRCPLL)

The FRCPLL mode is selected whenever the COSCx bits are '001'. In addition, this mode only functions when the direct or divide-by-2 FRC postscaler options are selected (IRCF<2:0> = 000 or 001).

When using the 4x or 8x PLL option, the output of the FRC postscaler may also be combined with the PLL to produce a nominal system clock of 16 MHz, 32 MHz or 64 MHz. Although somewhat less precise in frequency than using the Primary Oscillator with a crystal or resonator, it allows high-speed operation of the device without the use of external oscillator components.

For devices with the basic 4x PLL block, the output of the FRC postscaler block may also be combined with the PLL to produce a nominal system clock of either 16 MHz or 32 MHz. Although somewhat less precise in frequency than using the Primary Oscillator with a crystal or resonator, it still allows high-speed operation of the device without the use of external oscillator components.

When using the 96 MHz PLL block, the output of the FRC postscaler block may also be combined with the PLL to produce a nominal system clock of either 4 MHz, 8 MHz, 16 MHz or 32 MHz. It also produces a 48 MHz USB clock; however, this USB clock must be generated with the FRC Oscillator meeting the frequency accuracy requirement of USB for proper operation. Refer to the specific device data sheet for details on the FRC Oscillator electrical characteristics.

In cases where the frequency accuracy is not met for USB operation, the FRCPLL mode should not be used when USB is active.

Note:	Using FRC postscaler values, other than					
	'000'or '001', will cause the clock input to					
	the PLL to be below the operating					
	frequency input range and may cause					
	undesirable operation.					

# 3.11 Internal Low-Power RC Oscillator (LPRC)

The LPRC Oscillator is separate from the FRC and oscillates at a nominal frequency of 31 kHz. LPRC is the clock source for the Power-up Timer (PWRT), Watchdog Timer (WDT) and FSCM circuits. It may also be used to provide a low-frequency clock source option for the device, in those applications where power consumption is critical and timing accuracy is not required.

#### 3.11.1 ENABLING THE LPRC OSCILLATOR

Since it serves the Power-up Timer (PWRT) clock source, the LPRC Oscillator is enabled at POR events whenever the on-board voltage regulator is disabled. After the PWRT expires, the LPRC Oscillator will remain on if any one of the following is true:

- The FSCM is enabled.
- The WDT is enabled.
- The LPRC Oscillator is selected as the system clock (COSC<2:0> = 101).

If none of the above is true, the LPRC will shut off after the PWRT expires.

## 3.12 Fail-Safe Clock Monitor (FSCM)

The Fail-Safe Clock Monitor (FSCM) allows the device to continue to operate, even in the event of an oscillator failure. The FSCM function is enabled by programming the FSCMx (Clock Switch and Monitor) bits in CON-FIG3L<5:4>. FSCM is only enabled when the FSCM<1:0> bits (CONFIG3L<5:4>) = 00. When FSCM is enabled, the internal LPRC Oscillator will run at all times (except during Sleep mode).

In the event of an oscillator failure, the FSCM will generate a clock failure trap and will switch the system clock to the FRC Oscillator. The user will then have the option to either attempt to restart the oscillator or execute a controlled shutdown. FSCM will monitor the system clock source regardless of its source or oscillator mode. This includes the Primary Oscillator for all oscillator modes and the Secondary Oscillator, SOSC, when configured as the system clock.

The FSCM module takes the following actions when switching to the FRC Oscillator:

- 1. The COSCx bits are loaded with '000'.
- 2. The CF Status bit is set to indicate the clock

#### failure.

Note: For more information about the oscillator failure trap, refer to Section 10.0 "Interrupts".

## 3.12.1 FSCM DELAY

On a POR, BOR or wake from Sleep mode event, a nominal delay (TFSCM) may be inserted before the FSCM begins to monitor the system clock source. The purpose of the FSCM delay is to provide time for the oscillator and/or PLL to stabilize when the PWRT is not utilized. The FSCM delay will be generated after the internal System Reset signal, SYSRST, has been released. Refer to Section 28.4 "Fail-Safe Clock Monitor" for FSCM delay timing information.

The TFSCM interval is applied whenever the FSCM is enabled and the EC, HS or SOSC Oscillator modes are selected as the system clock.

Note:	Refer to the "Electrical Characteristics"
	section of the specific device data sheet
	for TFSCM specification values.

#### 3.12.2 FSCM AND SLOW OSCILLATOR START-UP

If the chosen device oscillator has a slow start-up time coming out of POR, BOR or Sleep mode, it is possible that the FSCM delay will expire before the oscillator has started. In this case, the FSCM will initiate a clock failure trap. As this happens, the COSCx bits are loaded with the FRC Oscillator selection. This will effectively shut off the original oscillator that was trying to start. The user can detect this situation and initiate a clock switch back to the desired oscillator in the Trap Service Routine (TSR).

## 3.12.3 FSCM AND WDT

The FSCM and the WDT both use the LPRC Oscillator as their time base. In the event of a clock failure, the WDT is unaffected and continues to run on the LPRC.

## 3.13 Clock Switching Operation

With few limitations, applications are free to switch between any of the four clock sources (Primary, SOSC, FRC and LPRC) under software control and at any time. To limit the possible side effects that could result from this flexibility, PIC18F devices have a safeguard lock built into the switch process.

Note:	Primary Oscillator mode has three different submodes (MS, HS and EC), which are determined by the POSCMDx Configura- tion bits. While an application can switch to and from Primary Oscillator mode, in soft- ware, it cannot switch between the different primary submodes without reprogramming the device.
-------	--

## 3.13.1 ENABLING CLOCK SWITCHING

To enable clock switching, the FCKSM1 Configuration bit must be programmed to '0'. If the FCKSM1 Configuration bit is unprogrammed ('1'), the clock switching function and Fail-Safe Clock Monitor function are disabled; this is the default setting.

The NOSCx control bits (OSCCON<2:0>) do not control the clock selection when clock switching is disabled. However, the COSCx bits (OSCCON<6:4>) will reflect the clock source selected by the FOSC Configuration bits.

#### 3.13.2 OSCILLATOR SWITCHING SEQUENCE

At a minimum, performing a clock switch requires this basic sequence:

- 1. If desired, read the COSCx bits (OSCCON<6:4>) to determine the current oscillator source.
- Clear the CLKLOCK bit (OSCCON2<7>) to enable writes to the NOSCx bits (OSCCON<2:0>).
- 3. Write the appropriate value to the NOSCx control bits (OSCCON<2:0>) for the new oscillator source.

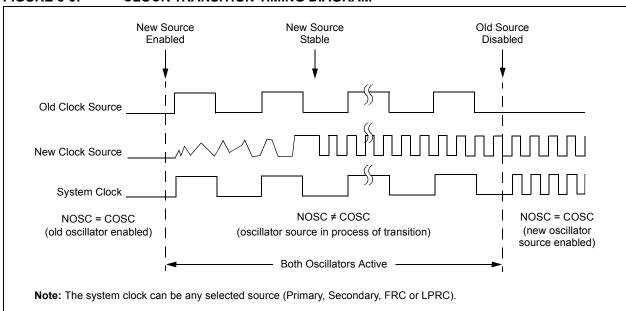

Once the basic sequence is completed, the system clock hardware responds automatically as follows:

 The clock switching hardware compares the COSC Status bits with the new value of the NOSC control bits. If they are the same, then the clock switch is a redundant operation. If they are different, then a valid clock switch has been initiated.

- The new oscillator is turned on by the hardware if it is not currently running. If a crystal oscillator must be turned on, the hardware will wait until the OST expires. If the new source is using the PLL, then the hardware waits until a PLL lock is detected (LOCK = 1).
- 3. The hardware waits for the new clock source to stabilize and then performs the clock switch.
- 4. The NOSCx bit values are transferred to the COSCx Status bits.
- 5. The old clock source is turned off at this time, with the exception of LPRC (if WDT or FSCM is enabled) or SOSC (if it is enabled by one of the timer sources).

The timing of the transition between clock sources is shown in Figure 3-9.

- **Note 1:** The processor will continue to execute code throughout the clock switching sequence. Timing-sensitive code should not be executed during this time.
  - 2: Direct clock switches between any Primary Oscillator mode with PLL and FRCPLL mode are not permitted. This applies to clock switches in either direction. In these instances, the application must switch to FRC mode as a transition clock source between the two PLL modes.

## FIGURE 3-9: CLOCK TRANSITION TIMING DIAGRAM

A recommended code sequence for a clock switch includes the following:

- 1. Disable interrupts during the OSCCON register unlock and write sequence.
- Clear the CLKLOCK bit (OSCCON2<7>) to enable writes to the NOSCx bits (OSCCON<2:0>).
- 3. Write new oscillator source to NOSCx control bits.
- 4. Continue to execute code that is not clocksensitive (optional).
- 5. Invoke an appropriate amount of software delay (cycle counting) to allow the selected oscillator and/or PLL to start and stabilize.
- 6. Check to see if COSC contains the new oscillator values that were requested in Step 3.

#### 3.13.2.1 Clock Switching Considerations

When incorporating clock switching into an application, users should keep certain things in mind when designing their code.

- If the new clock source is a crystal oscillator, the clock switch time will be dominated by the oscillator start-up time.
- If the new clock source does not start, or is not present, the clock switching hardware will wait indefinitely for the new clock source. The user can detect this situation because the COSCx bits will not change to reflect the new desired oscillator settings.
- Switching to a low-frequency clock source, such as the Secondary Oscillator, will result in very slow device operation.
  - **Note:** The application should not attempt to switch to a clock with a frequency lower than 100 kHz when the FSCM is enabled. Clock switching in these instances may generate a false oscillator fail trap and result in a switch to the Internal Fast RC Oscillator.

#### 3.13.3 ACTIVE CLOCK TUNING (ACT) MODULE

The Active Clock Tuning (ACT) module continuously adjusts the 8 MHz internal oscillator, using an available external reference, to achieve  $\pm$  0.20% accuracy. This eliminates the need for a high-speed, high-accuracy external crystal when the system has an available lower speed, lower power, high-accuracy clock source available. Systems implementing a Real-Time Clock Calendar (RTCC) or a full-speed USB application can take full advantage of the ACT module.

#### 3.13.3.1 Active Clock Tuning Operation

The ACT module defaults to the disabled state after any Reset. When the ACT module is disabled, the user can write to the TUN<6:0> bits in the OSCTUNE register to manually adjust the 8 MHz internal oscillator.

The module is enabled by setting the ACTEN bit of the ACTCON register. When enabled, the ACT module takes control of the OSCTUNE register. The ACT module uses the selected ACT reference clock to tune the 8 MHz internal oscillator to an accuracy of 8 MHz  $\pm$  0.2%. The tuning automatically adjusts the OSCTUNE register every reference clock cycle.

#### 3.13.3.2 Active Clock Tuning Source Selection

The ACT reference clock is selected with the ACTSRC bit of the ACTCON register. The reference clock sources are provided by the:

- USB module in full-speed operation (ACT\_clk)
- Secondary clock at 32.768 kHz (SOSC\_clk)

#### 3.13.3.3 ACT Lock Status

The ACTLOCK bit will be set to '1', when the 8 MHz internal oscillator is successfully tuned.

The bit will be cleared by the following conditions:

- Out of Lock condition
- Device Reset
- · Module is disabled

#### 3.13.3.4 ACT Out-of-Range Status

If the ACT module requires an OSCTUNE value outside the range to achieve  $\pm$  0.20% accuracy, then the ACT Out-of-Range (ACTORS) Status bit will be set to '1'.

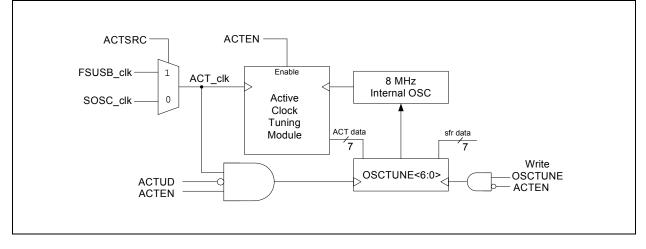

An out-of-range status can occur:

- When the 8 MHZ internal oscillator is tuned to its lowest frequency and the next ACT\_clk event requests a lower frequency.
- When the 8 MHZ internal oscillator is tuned to its highest frequency and the next ACT\_clk event requests a higher frequency.

When the ACT out-of-range event occurs, the 8 MHz internal oscillator will continue to use the last written OSCTUNE value. When the OSCTUNE value moves back within the tunable range and ACTLOCK is established, the ACTORS bit is cleared to '0'.

- Note 1: When the ACT module is enabled, the OSCTUNE register is only updated by the module. Writes to the OSCTUNE register by the user are inhibited, but reading the register is permitted.
  - **2:** After disabling the ACT module, the user should wait three instructions before writing to the OSCTUNE register.

## 3.13.4 ABANDONING A CLOCK SWITCH

In the event the clock switch does not complete, it can be abandoned by setting the NOSCx bits to their previous values. This abandons the clock switch process, stops and resets the OST (if applicable), and stops the PLL (if applicable).

A clock switch procedure can be aborted at any time. A clock switch that is already in progress can also be aborted by performing a second clock switch.

#### 3.13.5 ENTERING SLEEP MODE DURING A CLOCK SWITCH

If the device enters Sleep mode during a clock switch operation, the operation is abandoned. The processor keeps the old clock selection and the NOSCx bits return to their previous values (the same as COSC). The SLEEP instruction is then executed normally.

## 3.14 Two-Speed Start-Up

Two-Speed Start-up is an automatic clock switching feature that is independent of the manually controlled clock switching previously described. It helps to minimize the latency period, from oscillator start-up to code execution, by allowing the microcontroller to use the FRC Oscillator as a clock source until the primary clock source is available. This feature is controlled by the IESO Configuration bit (CONFIG2L<7>) and operates independently of the state of the FSCM Configuration bits.

Two-Speed Start-up is particularly useful when an external oscillator is selected by the FOSCx Configuration bits, and a crystal-based oscillator (either a Primary or Secondary Oscillator) may have a longer start-up time. As an internal RC Oscillator, the FRC clock source is available almost immediately following a POR or device wake-up.

With Two-Speed Start-up, the device starts executing code on POR in its default oscillator configuration (FRC). It continues to operate in this mode until the external oscillator source, specified by the FOSCx Configuration bits, becomes stable; at which time, it automatically switches to that source.

Two-Speed Start-up is used on wake-up from the powersaving Sleep mode. The device uses the FRC clock source until the selected primary clock is ready. It is not used in Idle mode, as the device will be clocked by the currently selected clock source until the primary clock source becomes available.

## 3.14.1 SPECIAL CONSIDERATIONS FOR USING TWO-SPEED START-UP

While using the FRC Oscillator in Two-Speed Start-up, the device still obeys the normal command sequences for entering power-saving modes, including SLEEP and IDLE instructions. In practice, this means that user code can change the NOSC<2:0> bit settings or issue #SLEEP instructions before the OST times out. This would allow an application to briefly wake-up, perform routine "housekeeping" tasks and return to Sleep before the device starts to operate from the external oscillator.

User code can also check which clock source is currently providing the device clocking by checking the status of the COSC<2:0> bits against the NOSC<2:0> bits. If these two sets of bits match, the clock switch has been completed successfully and the device is running from the intended clock source; the Primary Oscillator is providing the clock. Otherwise, FRC is providing the clock during wake-up from Reset or Sleep mode.

# 3.15 Reference Clock Output Module (REFO1 and REFO2)

#### 3.15.1 APPLICATIONS

The PIC18F97J94 family has two Reference Clock Output modules. Each of the Reference Clock Output modules provides the user with the ability to send out a programmed output clock onto the REFO1or REFO2 pins.

#### 3.15.2 REFERENCE CLOCK SOURCE

The module provides the ability to select one of the following clock sources:

- Primary Crystal Oscillator (POSC)
- Secondary Crystal Oscillator (SOSC)
- 32.768 kHz Internal Oscillator (INTOSC)
- Fast Internal Oscillator (FRC)
- Raw System Clock (sys\_clk)
- Peripheral Clock (p1\_clk)

It includes a programmable clock divider with ratios ranging from 1:1 to 1:65534.

When the clock source is a crystal or internal oscillator, the RSLP bit (REFOxCON<3> can be set to continue REFOx operation while the device is in Sleep Mode.

### 3.15.3 CLOCK SYNCHRONIZATION

The Reference Clock Output is enabled only once (ON = 1). Note that the source of the clock and the divider values should be chosen prior to the bit being set to avoid glitches on the REFO output.

Once the ON bit is set, its value is synchronized to the reference clock domain to enable the output. This ensures that no glitches will be seen on the output. Similarly, when the ON bit is cleared, the output and the associated output enable signals will be synchronized, and disabled on the falling edge of the reference clock. Note that with large divider values, this will cause the REFO to be enabled for some period after ON is cleared.

#### 3.15.4 OPERATION IN SLEEP MODE

If any clock source, other than the peripheral clock, is used as a base reference (i.e., ROSEL<3:0>  $\neq$  0001), the user has the option to configure the behavior of the oscillator in Sleep mode. The RSLP Configuration bit determines if the oscillator will continue to run in Sleep. If RSLP = 0, the oscillator will be shut down in Sleep (assuming no other consumers are requesting it). If RSLP = 1, the oscillator will continue to run in Sleep.

The Reference Clock Output is synchronized with the Sleep signal to avoid any glitches on its output.

#### 3.15.5 MODULE ENABLE SIGNAL

The REFOx module may be enabled or disabled using the REFOxMD register bit (PMD3, bit 1 or 0). The module also needs to be turned on using the ON bit (REFO1CON<7>).

#### 3.15.5.1 Registers and Bits

This module provides the following device registers and/or bits:

- REFOxCON Reference Clock Output Control Register
- REFOxCON1 Reference Clock Output Control 1 Register
- REFOxCON2 Reference Clock Output Control 2 Register
- REFOxCON3 Reference Clock Output Control 3 Register

## 4.0 POWER-MANAGED MODES

All PIC18F97J94 Family devices offer a number of built-in strategies for reducing power consumption. These strategies can be particularly useful in applications, which are both power-constrained (such as battery operation), yet require periods of full-power operation for timing-sensitive routines (such as serial communications).

Aside from their low-power architecture, these devices include an expanded range of dedicated hardware features that allow the microcontroller to reduce power consumption to even lower levels when long-term hibernation is required, and still be able to resume operation on short notice.

The device has four power-saving features:

- · Instruction-Based Power-Saving Modes
- Hardware-Based Power Reduction Features
- Microcontroller Clock Manipulation
- Selective Peripheral Control

Combinations of these methods can be used to selectively tailor an application's power consumption, while still maintaining critical or timing-sensitive application features. However, it is more convenient to discuss the strategies separately.

#### 4.1 Overview of Power-Saving Modes

In addition to full-power operation, otherwise known as Run mode, PIC18F97J94 Family devices offer three instruction-based, power-saving modes and one hardware-based mode. In descending order of power consumption, they are:

- Idle
- Sleep (including retention Sleep)
- · Deep Sleep (with and without retention)
- VBAT (with and without RTCC)

By powering down all four modes, different functional areas of the microcontroller allow progressive reductions of operating and Idle power consumption. In addition, three of the modes can be tailored for more power reduction at a trade-off of some operating features. Table 4-1 lists all of the operating modes (including Run mode, for comparison) in order of increasing power savings and summarizes how the microcontroller exits the different modes.

## TABLE 4-1: SUMMARY OF OPERATING MODES FOR PIC18F97J94 FAMILY DEVICES WITH VBAT POWER-SAVING FEATURES

**Note 1:** If RTCC is otherwise enabled in firmware.

2: Data retention in the DSGPR0, DSGPR1, DSGPR2 and DSGPR3 registers.

3: Deep Sleep WDT in Deep Sleep modes; WDT in all other modes.

4: Some select peripherals may continue to operate in this mode, using either the LPRC or an external clock source.

#### 4.2 Instruction-Based Power-Saving Modes

PIC18F97J94 Family devices have three instructionbased power-saving modes; two of these have additional features that allow for additional tailoring of power consumption. All three modes are entered through the execution of the SLEEP instruction. In descending order of power consumption, they are:

- Idle Mode: The CPU is disabled, but the system clock source continues to operate. Peripherals continue to operate, but can optionally be disabled.
- Sleep Modes: The CPU, system clock source and any peripherals that operate on the system clock source are disabled.
- Deep Sleep Modes: The CPU system clock source, and all the peripherals except RTCC and DSWDT are disabled. This is the lowest power mode for the device. The power to RAM and Flash is also disabled. Deep Sleep modes represent the lowest power modes available without removing power from the application.

Idle and Sleep modes are entered directly with the SLEEP statement. Having IDLEN (OSCCON<7>) set prior to the SLEEP statement will put the device into Idle mode. For Deep Sleep mode, it is necessary to set the DSEN bit (DSCONH<7>). To prevent inadvertent entry into Deep Sleep mode, and possible loss of data, the DSEN bit must be written to twice. The write need not be consecutive instructions; however, it is a better practice to write both, one after the other. It is also recommended to clear the DSCON1 register before setting the DSEN bit (Example 4-1).

Note: SLEEP\_MODE and IDLE\_MODE are constants defined in the Assembler Include file for the selected device.

#### EXAMPLE 4-1: SLEEP ASSEMBLY SYNTAX

bsf	DSCON1,7		
sleep			
or			
movlw	0x80		
movwf	DSCON1		
movwf	DSCON1		
sleep			

The instruction-based power-saving modes are exited as a result of several different hardware triggers. When the device exits one of these three operating modes, it is said to 'wake-up'. The characteristics of the powersaving modes are described in the subsequent sections.

#### 4.2.1 INTERRUPTS COINCIDENT WITH POWER SAVE INSTRUCTIONS

Any interrupt that coincides with the execution of a SLEEP instruction will be held off until entry into Sleep, Idle or Deep Sleep mode is completed. The device will then wake-up from the power-managed mode.

Interrupts that occur during the Deep Sleep unlock sequence will interrupt the mandatory unlock sequence and cause a failure to enter Deep Sleep. For this reason, it is recommended to disable all interrupts during the Deep Sleep unlock sequence.

#### 4.2.2 RETENTION REGULATOR

A second on-chip voltage regulator is used for power management in Sleep and Deep Sleep modes. This regulator, also known as the retention regulator, supplies core logic and other circuits with power at a lower VCORE level, about 1.2V nominal. Running these circuits at a lower voltage allows for an additional incremental power saving over the normal minimum VCORE level.

In Retention Sleep modes, using the regulator maintains the entire data RAM and its contents, instead of just a few protected registers. This allows the device to exit a power-saving mode and resume code execution as its previous state.

The retention regulator is controlled by the Configuration bit, RETEN (CONFIG7L<0>), and the SRETEN bit (RCON4<4>). The RETEN bit makes the retention regulator available for software control. By default (RETEN = 1), the regulator is disabled and the SRETEN bit has no effect. Programming RETEN (= 0) allows the SRETEN bit to control the regulator's operation, leaving its use in power-saving modes at the user's discretion.

Setting the SRETEN bit prior to executing the SLEEP instruction puts the device into Retention Sleep mode. If the DSEN bit was also unlocked and set prior to the instruction, the device will enter Retention Deep Sleep mode.

The retention regulator is not available outside of Sleep, Deep Sleep or VBAT modes. Enabling it while the device is operating in Run or Idle modes does not allow the device to operate at a lower level of VCORE.

## 4.2.3 IDLE MODE

When the device enters Idle mode, the following events occur:

- The CPU will stop executing instructions.
- · The WDT is automatically cleared.
- The system clock source will remain active and the peripheral modules, by default, will continue to operate normally from the system clock source. Peripherals can optionally be shut down in Idle mode using their 'Stop in Idle' control bit. (See peripheral descriptions for further details.)
- If the WDT or FSCM is enabled, the LPRC will also remain active.

The processor will wake-up from Idle mode on the following events:

- On any interrupt that is individually enabled.
- On any source of device Reset.
- On a WDT time-out.

Upon wake-up from Idle mode, the clock is reapplied to the CPU and instruction execution begins immediately, starting with the instruction following the SLEEP instruction, or the first instruction in the Interrupt Service Routine (ISR).

#### 4.2.3.1 Time Delays on Wake-up from Idle Mode

Unlike a wake-up from Sleep mode, there are no additional time delays associated with wake-up from Idle mode. The system clock is running during Idle mode, therefore, no start-up times are required at wake-up.

#### 4.2.3.2 Wake-up from Idle on Interrupt

Any source of interrupt that is individually enabled using the corresponding control bit in the PIEx register, will be able to wake-up the processor from Idle mode. When the device wakes from Idle mode, one of two options may occur:

- If the GIE bit is set, the processor will wake and the Program Counter will begin execution at the interrupt vector.
- If the GIE bit is not set, the processor will wake and the Program Counter will continue execution following the SLEEP instruction.

The PD Status bit (RCON<2>) is set upon wake-up.

#### 4.2.3.3 Wake-up from Idle on Reset

Any Reset, other than a Power-on Reset (POR), will wake-up the CPU from Idle mode on any device Reset, except a POR.

#### 4.2.3.4 Wake-up from Idle on WDT Time-out

If the WDT is enabled, then the processor will wake-up from Idle mode on a WDT time-out and continue code execution with the instruction following the SLEEP instruction that initiated Idle mode. Note that the WDT time-out does not reset the device in this case. The TO bit (RCON<3>) will be set.

#### 4.2.4 SLEEP MODES

Most 08KA101 family devices that incorporate powersaving features and VBAT, offer two distinct Sleep modes: Sleep mode and Retention Sleep mode. The characteristics of both Sleep modes are:

- The system clock source is shut down. If an onchip oscillator is used, it is turned off.
- The device current consumption will be optimum, provided no I/O pin is sourcing the current.
- The Fail-Safe Clock Monitor (FSCM) does not operate during Sleep mode since the system clock source is disabled.
- The LPRC clock will continue to run in Sleep mode if the WDT is enabled.
- If Brown-out Reset (BOR) is enabled, the Brownout Reset (BOR) circuit remains operational during Sleep mode.
- The WDT, if enabled, is automatically cleared prior to entering Sleep mode.
- Some peripherals may continue to operate in Sleep mode. These peripherals include I/O pins that detect a change in the input signal or peripherals that use an external clock input. Any peripheral that operates from the system clock source will be disabled in Sleep mode.

The processor will exit, or 'wake-up' from Sleep on one of the following events:

- On any interrupt source that is individually enabled
- · On any form of device Reset
- · On a WDT time-out

#### 4.2.4.1 Retention Sleep Mode

Retention Sleep mode allows for additional power savings over Sleep mode by maintaining key systems from the lower power retention regulator. When the retention regulator is used, the normal on-chip voltage regulator (operating at 1.8V nominal) is turned off and will enable a low-power (1.2V typical) regulator. By using a lower voltage, a lower total power consumption is achieved.

Retention Sleep also offers the advantage of maintaining the contents of the data RAM. As a trade-off, the wake-up time is longer than that for Sleep mode.

Retention Sleep mode is controlled by the SRETEN bit (RCON4<4>) and the RETEN Configuration bit, as described in Section 4.2.2, Retention Regulator.

## 4.3 Clock Source Considerations

When the device wakes up from either of the Sleep modes, it will restart the same clock source that was active when Sleep mode was entered. Wake-up delays for the different oscillator modes are shown in Table 4-3 and Table 4-4, respectively.

If the system clock source is derived from a crystal oscillator and/or the PLL, the Oscillator Start-up Timer (OST) and/or PLL lock times must be applied before the system clock source is made available to the device. As an exception to this rule, no oscillator delays are necessary if the system clock source is the Secondary Oscillator and it was running while in Sleep mode.

## 4.3.1 SLOW OSCILLATOR START-UP

The OST and PLL lock times may not have expired when the power-up delays have expired.

To avoid this condition, one can enable Two-Speed Start-up by the device that will run on FRC until the clock source is stable. Once the clock source is stable, the device will switch to the selected clock source.

#### 4.3.2 WAKE-UP FROM SLEEP ON INTERRUPT

Any source of interrupt that is individually enabled, using its corresponding control bit in the PIEx registers, can wake-up the processor from Sleep mode. When the device wakes from Sleep mode, one of two following actions may occur:

- If the GIE bit is set, the processor will wake and the Program Counter will begin execution at the interrupt vector.
- If the GIE bit is not set, the processor will wake and the Program Counter will continue execution following the SLEEP instruction that initiated Sleep mode.

#### 4.3.3 WAKE-UP FROM SLEEP ON RESET

All sources of device Reset will wake-up the processor from Sleep mode.

#### 4.3.4 WAKE-UP FROM SLEEP ON WATCHDOG TIME-OUT

If the Watchdog Timer (WDT) is enabled and expires while the device is in Sleep mode, the processor will wake-up. The SWDTEN Status bit (RCON2<5>) is set to indicate that the device resumed operation due to the WDT expiration. Note that this event does not reset the device. Operation continues from the instruction following the SLEEP instruction that initiated Sleep mode.

## 4.3.5 CONTROL BIT SUMMARY FOR SLEEP MODES

Table 4-2 shows the settings for the bits relevant to Sleep modes.

TABLE 4-2:	BIT SETTINGS FOR ALL
	SLEEP MODES

Mode	DSEN DSCONH<7>	Retention Regulator		
		RETEN CONFIG7L<0>	SRETEN RCON4<4>	State
Sleep	x	1	x	Disabled
	х	0	0	Disabled
Retention Sleep	x	0	1	Enabled

#### 4.3.6 WAKE-UP DELAYS

The restart delay, associated with waking up from Sleep and Retention Sleep modes, parallel each other in terms of clock start-up times. They differ in the time it takes to switch over from their respective regulators. The delays for the different oscillator modes are shown in Table 4-3 and Table 4-4, respectively.

### TABLE 4-3: DELAY TIMES FOR EXITING FROM SLEEP MODE

Clock Source		Exit Delay	Oscillator Delay	Notes
EC		Трм	_	1
ECPLL		Трм	Тьоск	1, 3
MS, HS		Трм	Tost	1, 2
MSPLL, HSPLL		Трм	TOST + TLOCK	1, 2, 3
SOSC	(Off during Sleep)	Трм	Tost	1, 2
	(On during Sleep)	Трм	_	1
FRC, FRC	DIV	Трм	TFRC	1, 4
LPRC	(Off during Sleep)	Трм	TLPRC	1, 4
	(On during Sleep)	Трм	_	1
FRCPLL		Трм	TLOCK	1, 3

**Note 1:** TPM = Start-up delay for program memory stabilization.

2: TOST = Oscillator Start-up Timer (OST); a delay of 1024 oscillator periods before the oscillator clock is released to the system.

- **3:** TLOCK = PLL lock time.
- 4: TFRC and TLPRC are RC Oscillator start-up times.

### TABLE 4-4: DELAY TIMES FOR EXITING FROM RETENTION SLEEP MODE

Clock Source		Exit Delay	Oscillator Delay	Notes
EC		TRETR + TPM	_	1, 2
ECPLL		TRETR + TPM	TLOCK	1, 2, 4
MS, HS		TRETR + TPM	Tost	1, 2, 3
MSPLL, HSPLL		TRETR + TPM	TOST + TLOCK	1, 2, 3, 4
SOSC	(Off during Sleep)	TRETR + TPM	Tost	1, 2, 3
	(On during Sleep)	TRETR + TPM	—	1, 2
FRC, FRC	DIV	TRETR + TPM	TFRC	1, 2, 5
LPRC	(Off during Sleep)	TRETR + TPM	TLPRC	1, 2, 5
	(On during Sleep)	TRETR + TPM	—	1, 2
FRCPLL		TRETR + TPM	TLOCK	1, 2, 4

**Note 1:** TRETR = Retention regulator start-up delay.

**2:** TPM = Start-up delay for program memory stabilization; applicable only when IPEN (RCON<7>) = 0.

**3:** TOST = Oscillator Start-up Timer; a delay of 1024 oscillator periods before the oscillator clock is released to the system.

**4:** TLOCK = PLL lock time.

5: TFRC and TLPRC are RC Oscillator start-up times.

# 4.4 Deep Sleep Modes

The Deep Sleep modes puts the device into its lowest power consumption states without requiring the use of external switches to remove power from the device. There are two modes available: Deep Sleep mode and Retention Deep Sleep mode.

During both Deep Sleep modes, the power to the microcontroller core is removed to reduce leakage current. Therefore, most peripherals and functions of the microcontroller become unavailable during Deep Sleep. However, a few specific peripherals and functions are powered directly from the VDD supply rail of the microcontroller, and therefore, can continue to function in Deep Sleep. In addition, four data memory locations, DSGPR0, DSGPR1, DSGPR2 and DSGPR3, are preserved for context information after an exit from Deep Sleep.

Deep Sleep has a dedicated Deep Sleep Brown-out Reset (DSBOR) and a Deep Sleep Watchdog Timer Reset (DSWDT) for monitoring voltage and time-out events in Deep Sleep mode. The DSBOR and DSWDT are independent of the standard BOR and WDT used with other power-managed modes (Run, Idle and Sleep).

Entering Deep Sleep mode clears the Deep Sleep Wake-up Source Registers (DSWAKEL and DSWAKEH). If enabled, the Real-Time Clock and Calendar (RTCC) continues to operate uninterrupted.

When a wake-up event occurs in Deep Sleep mode (by Reset, RTCC alarm, External Interrupt (INT0) or DSWDT), the device will exit Deep Sleep mode and rearm a Power-on Reset (POR). When the device is released from Reset, code execution will resume at the Reset vector.

### 4.4.1 RETENTION DEEP SLEEP MODE

In Retention Deep Sleep, the retention regulator is enabled, which allows the data RAM to retain data while all other systems are powered down. This also allows the device to return to code execution where it left off, instead of going through a POR-like Reset.

As a trade-off, Retention Deep Sleep mode has greater power consumption than Deep Sleep. However, it offers the lowest level of power consumption of the power-saving modes that still allows a direct return to code execution.

Retention Deep Sleep is controlled by the SRETEN bit (RCON4<4>) and the RETEN Configuration bit, as described in Section 4.2.2 "Retention Regulator".

#### 4.4.2 ENTERING DEEP SLEEP MODES

Deep Sleep modes are entered by:

- Setting the DSEN bit (DSCONH<7>)
- Executing the **SLEEP** instruction

To enter Retention Deep Sleep, the SRETEN bit must also be set prior to setting the DSEN bit (Example 4-1).

In order to minimize the possibility of inadvertently entering Deep Sleep, the DSEN bit must be set by two separate write operations. To enter Deep Sleep, the SLEEP instruction must be executed after setting the DSEN bit (i.e., the next instruction). If DSEN is not set when Sleep is executed, the device will enter a Sleep mode instead.

# 4.4.3 DEEP SLEEP WAKE-UP SOURCES

The device can be awakened from Deep Sleep modes by any of the following:

- MCLR
- POR
- RTCC Alarm
- INT0 Interrupt
- DSWDT Event

After waking from Deep Sleep mode, the device performs a POR. When the device is released from Reset, code execution will begin at the device's Reset vector.

The software can determine if the wake-up was caused from an exit from Deep Sleep mode by reading the DPSLP bit (RCON4<2>). If this bit is set, the POR was caused by a Deep Sleep exit. The DPSLP bit must be manually cleared by the software.

The software can determine the wake-up event source by reading the DSWAKE registers. These registers are cleared automatically when entering Deep Sleep mode, so software should read these registers after exiting Deep Sleep mode or before re-enabling this mode.

#### 4.4.4 CLOCK SELECTION ON WAKE-UP FROM DEEP SLEEP MODE

For Deep Sleep mode, the processor will restart with the default oscillator source, selected with the FOSCx Configuration bits. On wake-up from Deep Sleep, a POR is generated internally, hence, the system resets to its POR state with the exception of the RCONx, DSCONH/L and DSGPRx registers.

For Retention Deep Sleep, the processor restarts with the same clock source that was selected before entering Retention Deep Sleep mode. Wake-up is similar to that of Sleep and Retention Sleep modes.

# 4.4.5 SAVING CONTEXT DATA WITH THE DSGPRx REGISTERS

As exiting Deep Sleep mode causes a POR, most Special Function Registers (SFRs) reset to their default POR values. In addition, because the core power is not supplied in Deep Sleep mode, information in data RAM may be lost when exiting this mode. Applications which require critical data to be saved prior to Deep Sleep may use the Deep Sleep General Purpose registers, DSGPR0, DSGPR1, DSGPR2 and DSGPR3. Unlike other SFRs, the contents of these registers are preserved while the device is in Deep Sleep mode. After exiting Deep Sleep, software can restore the data by reading the registers and clearing the RELEASE bit (DSCONL<0>).

Any data stored in the DSGPRx registers must be written twice. Like other Deep Sleep control features, the write operations do not need to be sequential. However, back-to-back writes are a recommended programming practice.

Since the contents of data RAM are maintained in Retention Deep Sleep, the use of the DSGPRx registers to store critical data is not necessary in this mode.

#### 4.4.6 I/O PINS DURING DEEP SLEEP

During Deep Sleep, general purpose I/O pins retain their previous states. Pins that are configured as inputs (TRIS bit is set), prior to entry into Deep Sleep, remain high-impedance during Deep Sleep.

Pins that are configured as outputs (TRIS bit is clear), prior to entry into Deep Sleep, will remain as output pins during Deep Sleep. While in this mode, they will drive the output level determined by their corresponding LAT bit at the time of entry into Deep Sleep.

Once the device wakes back up, all I/O pins will continue to maintain their previous states, even after the device has finished the POR sequence and is executing application code again. Pins configured as inputs during Deep Sleep will remain high-impedance and pins configured as outputs will continue to drive their previous value. After waking up, the TRIS and LAT registers will be reset. If firmware modifies the TRIS and LAT values for the I/O pins, they will not immediately go to the newly configured states. Once the firmware clears the RELEASE bit (DSCONL<0>), the I/O pins are "released". This causes the I/O pins to take the states configured by their respective TRIS and LAT bit values.

If the Deep Sleep BOR (DSBOR) is enabled, and a DSBOR event occurs during Deep Sleep (or VDD is hard-cycled to VSS), the I/O pins will be immediately released, similar to clearing the RELEASE bit. All previous state information will be lost, including the general purpose DSGPR0, DSGPR1, DSGPR2 and DSGPR3 contents. DSGPRx register contents will be maintained if the VBAT pin is powered.

If a MCLR Reset event occurs during Deep Sleep, the I/O pins will also be released automatically, but in this case, the DSGPR0, DSGPR1, DSGPR2 and DSGPR3 contents will remain valid.

In case of MCLR Reset and all other Deep Sleep wakeup cases, application firmware needs to clear the RELEASE bit (DSCONL<0>) in order to reconfigure the I/ O pins.

### 4.4.7 DEEP SLEEP WATCHDOG TIMER (DSWDT)

Deep Sleep has its dedicated WDT (DSWDT). It is enabled through the DSWDTEN Configuration bit. The DSWDT is equipped with a postscaler for time-outs of 2.1 ms to 25.7 days, configurable through the Configuration bits, DSWDTPS<4:0>. Entering Deep Sleep mode automatically clears the DSWDT.

The DSWDT also has a configurable reference clock source for selecting the LPRC or SOSC. The reference clock source is configured through the DSWDTOSC Configuration bit.

Under certain circumstances, it is possible for the DSWDT clock source to be off when entering Deep Sleep mode. In this case, the clock source is turned on automatically (if DSWDT is enabled), without the need for software intervention. However, this can cause a delay in the start of the DSWDT counters. In order to avoid this delay, when using SOSC as a clock source, the application can activate SOSC prior to entering Deep Sleep mode.

#### 4.4.8 DEEP SLEEP LOW-POWER BROWN-OUT RESET

Devices with a Deep Sleep Power-Saving mode also have a dedicated BOR for Deep Sleep modes (DSBOR). It has a trip point range of 1.7V-2.3V nominal and is enabled through the DSBOREN (CONFIG7L<3>) Configuration bit.

When the device enters a Deep Sleep mode and receives a DSBOR event, the device will not wake-up and will remain in the Deep Sleep mode. When a valid wake-up event occurs and causes the device to exit Deep Sleep mode, software can determine if a DSBOR event occurred during Deep Sleep mode by reading the BOR (DSWAKEL<6>) Status bit.

### 4.4.9 RTCC AND DEEP SLEEP

The RTCC can operate uninterrupted during Deep Sleep modes. It can wake-up the device from Deep Sleep by configuring an alarm. The RTCC clock source is configured with the RTCC Clock Select bits, RTCCLKSEL<1:0>. The available reference clock sources are the LPRC and SOSC. If the LPRC is used, the RTCC accuracy will directly depend on the LPRC tolerance.

If the RTCC is not required, Deep Sleep mode with the RTCC disabled, affords the lowest power consumption of any of the instruction-based power-saving modes.

# 4.4.10 CONTROL BIT SUMMARY FOR SLEEP MODES

Table 4-5 shows the settings for the bits relevant toDeep Sleep modes.

Instruction-Based	DSEN	Re	DSWDTEN		
Mode	(DSCONH<7>)	RETEN (CONFIG7L<0>)	SRETEN (RCON4<4>)	State	(CONFIG8H<0>)
Retention Deep Sleep	1	0	1	Enabled	0
Deep Sleep	1	1	х	Disabled	х

# TABLE 4-5: BIT SETTINGS FOR ALL DEEP SLEEP MODES

### 4.4.11 WAKE-UP DELAYS

The Reset delays associated with wake-up from Deep Sleep and Retention Deep Sleep modes, in different oscillator modes, are provided in Table 4-6 and Table 4-7, respectively.

Note: The PMSLP bit (RCON4<0>) allows the voltage regulator to be maintained during Sleep modes.

# TABLE 4-6: DELAY TIMES FOR EXITING FROM DEEP SLEEP MODE

Clock Source		k Source Exit Delay		Notes
EC		TDSWU	_	
ECPLL		TDSWU	ТLОСК	1, 3
MS, HS		TDSWU	Тоѕт	1, 2
MSPLL, HS	SPLL	TDSWU	TOST + TLOCK	1, 2, 3
SOSC	(Off during Sleep)	TDSWU	Тоѕт	1, 2
	(On during Sleep)	TDSWU	—	1

LPRC	(Off during Sleep)	TDSWU	TLPRC	1, 4
	(On during Sleep)	TDSWU	—	1
FRCPLL		TDSWU	TFRC + TLOCK	1, 3, 4

**Note 1:** TDSWU = Deep Sleep wake-up delay.

2: TOST = Oscillator Start-up Timer; a delay of 1024 oscillator periods before the oscillator clock is released to the system.

- **3:** TLOCK = PLL lock time.
- 4: TFRC and TLPRC are RC Oscillator start-up times.

TABLE 4-7:	DELAY TIMES FOR EXITING RETENTION DEEP SLEEP MODE	

Clock Source		Exit Delay	Oscillator Delay	Notes
EC		TRETR + TPM	_	1, 2, 6
ECPLL		TRETR + TPM	TLOCK	1, 2, 4, 6
MS, HS		TRETR + TPM	Tost	1, 2, 3, 6
MSPLL, HSPLL		TRETR + TPM	TOST + TLOCK	1, 2, 3, 4, 6
SOSC	Off during Sleep	TRETR + TPM	Tost	1, 2, 3, 6
	On during Sleep	TRETR + TPM	—	1, 2, 6
FRC, FRCD	IV	TRETR + TPM	TFRC	1, 2, 5, 6
LPRC:	Off during Sleep	TRETR + TPM	TLPRC	1, 2, 5, 6
	On during Sleep	TRETR + TPM	—	1, 2, 6
FRCPLL		TRETR + TPM	TLOCK	1, 2, 3, 6

**Note 1:** TPM = Start-up delay for program memory stabilization; applicable only when IPEN (RCON<7>) = 0.

**2:** TRETR = Retention regulator start-up delay.

**3:** TOST = Oscillator Start-up Timer (OST); a delay of 1024 oscillator periods before the oscillator clock is released to the system.

**4:** TLOCK = PLL lock time.

5: TFRC and TLPRC = RC Oscillator start-up times.

6: TFLASH = Flash program memory ready delay. Setting the PMSLP bit will provide a faster wake-up.

# 4.5 VBAT Mode

VBAT mode is a hardware-based power mode that maintains only the most critical operations when a power loss occurs on VDD. The mode does this by powering these systems from a back-up power source connected to the VBAT pin. In this mode, the RTCC can run even when there is no power on VDD.

VBAT mode is entered whenever power is removed from VDD. An on-chip power switch detects the power loss from the VDD and connects the VBAT pin to the retention regulator. This provides power at 1.2V to maintain the retention regulator, as well as the RTCC, with its clock source (if enabled) and the Deep Sleep General Purpose (DSGPRx) registers (Figure 4-1). Entering VBAT mode requires that a power source, distinct from the main VDD power source, be available on VBAT and that VDD be completely removed from the VDD pin(s). Removing VDD can be either unintentional, as in a power failure, or as part of a deliberate power reduction strategy.

As with Deep Sleep modes, the contents of the Deep Sleep General Purpose (DSGPRx) registers are maintained by the retention regulator. Since the power loss on VDD may be unforeseen, it is recommended to load any data to be saved in these registers in advance.

Any data stored in the DSGPRx registers must be written twice. The write operations do not need to be sequential; however, back-to-back writes are a recommended programming practice.

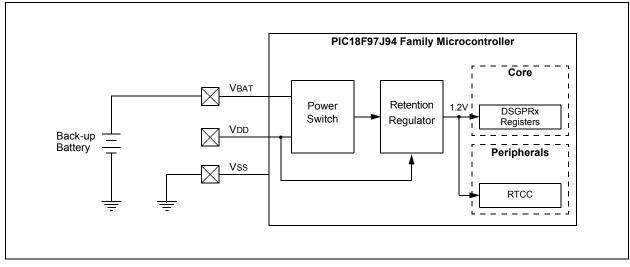

FIGURE 4-1: VBAT POWER TOPOLOGY

# 4.5.1 WAKE-UP FROM VBAT MODES

When VDD is restored to a device in VBAT mode, it automatically wakes. Wake-up occurs with a POR, after which the device starts executing code from the Reset vector. All SFRs, except the Deep Sleep semaphores and RTCC registers are reset to their POR values. If the RTCC was not configured to run during VBAT mode, it will remain disabled and RTCC will not run. Wake-up timing is similar to that for a normal POR.

Wake-up from VBAT mode is identified by checking the state of the VBAT bit (RCON3<0>). If this bit is set when the device is awake and starting to execute the code from the Reset vector, it indicates that the exit was from VBAT mode. To identify future VBAT wake-up events, the bit must be cleared in software.

When a POR event occurs with no battery connected to the VBAT pin, the VBPOR bit (RCON3<1>) becomes set. On the device, if there is no battery connected to the VBAT pin, VBPOR will indicate that the battery needs to be connected to the VBAT pin.

In addition, if the VBAT power source falls below the level needed for Deep Sleep semaphore operation while in VBAT mode (e.g., the battery has been drained), the VBPOR bit will be set. VBPOR is also set when the microcontroller is powered up the very first time, even if power is supplied to VBAT.

# 4.6 Saving Context Data with the DSGPRx Registers

As exiting VBAT causes a POR, most Special Function Registers reset to their default POR values. In addition, because the core power is not supplied in VBAT mode, information in data RAM will be lost when exiting this mode. Applications which require critical data to be saved, should be saved in DSGPR0, DSGPR1, DSGPR2 and DSGPR3.

Any data stored to the DSGPRx registers must be written twice. The write operations do not need to be sequential. However, back-to-back writes are a recommended programming practice.

After exiting VBAT mode, software can restore the data by reading the registers.

# 4.6.1 I/O PINS DURING VBAT MODE

All I/O pins should be maintained at VSS level; no I/O pins should be given VDD (refer to **"Absolute Maximum Ratings**<sup>(†)</sup>" in **Section 30.0 "Electrical Specifications**") during VBAT mode. The only exceptions are the SOSCI and SOSCO pins, which maintain their states if the Secondary Oscillator is being used as the RTCC clock source. It is the user's responsibility to restore the I/O pins to their proper states, using the TRIS and LAT bits, once VDD has been restored.

# 4.7 Selective Peripheral Power Control

Sleep and Idle modes allow users to substantially reduce power consumption by slowing or stopping the CPU clock. Even so, peripheral modules still remain clocked, and thus, consume some amount of power. There may be cases where the application needs what these modes do not provide: the ability to allocate limited power resources to the CPU while eliminating power consumption from the peripherals. The 08KA101 family addresses this requirement by allowing peripheral modules to be selectively enabled or disabled, reducing or eliminating their power consumption.

# 4.7.1 DISABLING PERIPHERAL MODULES

Most of the peripheral modules in the 08KA101 family architecture can be selectively disabled, reducing, or essentially eliminating, their power consumption during all operating modes. Two different options are available to users, each with a slightly different effect.

# 4.7.2 MODULE ENABLE BIT (XXXEN)

Many peripheral modules have a Module Enable bit, generically named, "XXXEN", usually located in Bit Position 7 of their control registers (or Primary Control registers for more complex modules). Here, "XXX" represents the mnemonic form for the module of the module name. For example, the enable bit for an MSSPx module is "SSPEN", and so on. The bit is provided for all serial and parallel communication modules and the Real-Time Clock (RTC). Clearing this bit disables the module's operation; however, it continues to receive clock signals and draw a minimal amount of current.

As with all earlier PIC<sup>®</sup> MCU devices, timers continue to be under selective operation and are controlled by their own TON bit, also located in Position 7. The A/D Converter also has a legacy enable bit, ADON, that has the same function as the XXXEN bits. I/O ports and features associated with them, such as input change notification and input capture, do not have their own module enable bits, since their operation is secondary to other modules. Disabling modules not required for a particular application, in this manner, allows for the selective and dynamic adjusting power consumption, under software control, as the application is running.

#### 4.7.3 PERIPHERAL MODULE DISABLE BIT (XXMD)

All peripheral modules (except for I/O ports) also have a second control bit that can disable their functionality. These bits, known as the Peripheral Module Disable (PMD) bits, are generically named, "XXMD" (using "XX" as the mnemonic version of the module's name), as shown in **Section 4.7.2** "**Module Enable Bit** (XXXEN)"). These bits are located in the PMDx SFRs. In contrast to the module enable bits, the XXMD bit must be set (= 1) to disable the module.

While the PMD and module enable bits both disable a peripheral's functionality, the PMD bit completely shuts down the peripheral, effectively powering down all circuits and removing all clock sources. This has the additional effect of making any of the module's control and buffer registers, mapped in the SFR space, unavailable for operations. In other words, when the PMD bit is used to disable a module, the peripheral ceases to exist until the PMD bit is cleared. This differs from using the module enable bit, which allows the peripheral to be reconfigured and buffer registers preloaded, even when the peripheral's operations are disabled.

The PMD bit is most useful in highly power-sensitive applications, where even tiny savings in power consumption can determine the ability of an application to function. In these cases, the bits can be set before the main body of the application to remove those peripherals that will not be needed at all.

# 5.0 RESET

The 08KA101 family devices differentiate between various kinds of Reset:

- a) Power-on Reset (POR)
- b) MCLR Reset
- c) Watchdog Timer (WDT) Reset
- d) Configuration Mismatch (CM)
- e) Brown-out Reset (BOR)
- f) RESET Instruction
- g) Stack Underflow/Overflow Reset

This section discusses Resets generated by MCLR, POR and BOR, and covers the operation of the various start-up timers. For information on WDT Resets, see **Section 28.2 "Watchdog Timer (WDT)"**. For Stack Reset events, see **Section 6.1.4.4 "Stack Full and Underflow Resets"**. For Deep Sleep mode, see **Section 4.4 "Deep Sleep Modes"**. A simplified block diagram of the On-Chip Reset Circuit is shown in Figure 5-1.

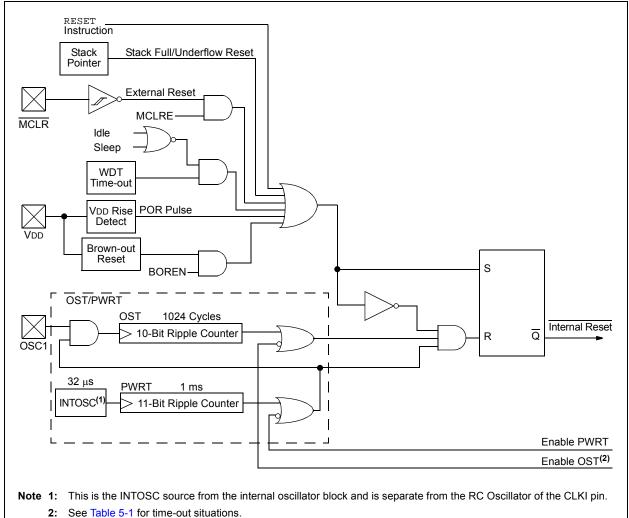

# 5.1 RCON Registers

Device Reset events are tracked through the RCON, RCON2, RCON3 and RCON4 registers (Register 5-1, Register 5-2, Register 5-3 and Register 5-4). The register bits indicate that a specific Reset event has occurred. Depending on the definition, Status bits may be set or cleared by the event, and re-initialized by the application, after the event to the opposite state. Setting or clearing Reset Status bits does not cause a Reset.

The state of these flag bits, taken together, can be read to indicate the type of Reset that just occurred.

The RCON register also has a control bit for setting interrupt priority (IPEN). Interrupt priority is discussed in **Section 10.0 "Interrupts"**.

# 5.2 Power-on Reset (POR)

The PIC18F97J94 family has two types of Power-on Resets:

- POR
- VBAT POR

POR is the legacy PIC18J series Power-on Reset which monitors core power supply. The second, VBAT POR, monitors voltage on the VBAT pin. These POR circuits use the same technique to enable and monitor their respective power source for adequate voltage levels to ensure proper chip operation. There are two threshold voltages associated with them. The first voltage is the device threshold voltage, VPOR. The device threshold voltage is the voltage at which the POR module becomes operable. The second voltage associated with a POR event is the POR circuit threshold voltage. Once the correct threshold voltage is detected, a power-on event occurs and the POR module hibernates to minimize current consumption.

A power-on event generates an internal POR pulse when a VDD rise is detected. The device supply voltage characteristics must meet the specified starting voltage, VPOR, and rise rate requirements, SVDD, to generate the POR pulse. In particular, VDD must fall below VPOR before a new POR is initiated. For more information on the VPOR and VDD rise rate specifications, refer to **Section 30.0 "Electrical Specifications**".

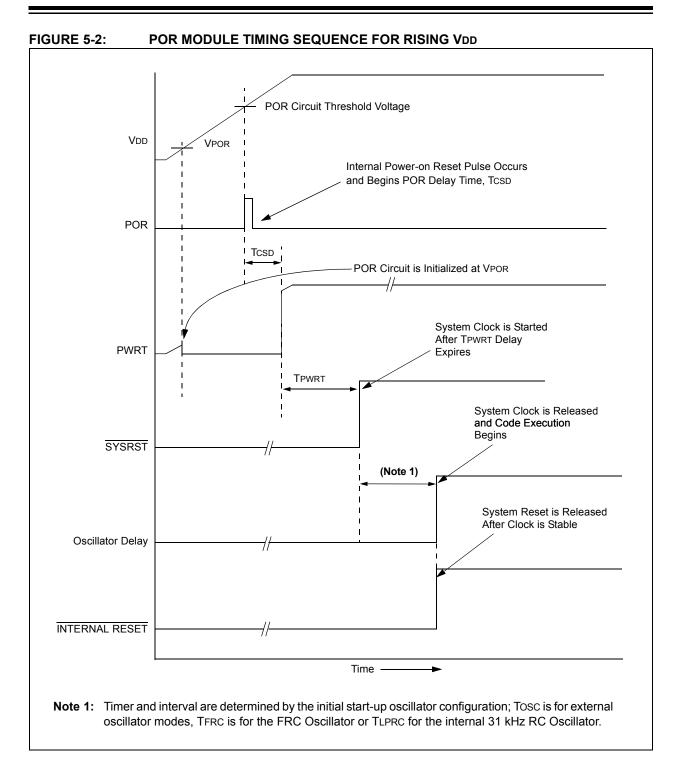

### 5.2.1 POR CIRCUIT

The POR circuit behaves differently than VBAT POR once the POR state becomes active. The internal POR pulse resets the POR timer and places the device in the Reset state. The POR also selects the device clock source identified by the Oscillator Configuration bits. After the POR pulse is generated, the POR circuit inserts a small delay, TCSD, to ensure that internal device bias circuits are stable. After the expiration of TCSD, a delay, TPWRT, is always inserted every time the device resumes operation after any power-down. During this time, code execution is disabled. The PWRT is used to extend the duration of a power-up sequence to permit the on-chip band gap and regulator to stabilize and to load the Configuration Word settings. The on-chip regulator is always enabled and its stabilization time is shorter than other concurrently running delays, and does not extend start-up time.

The power-on event clears the BOR and POR Status bits (RCON<1:0>); it does not change for any other Reset event. POR is not reset to '1' by any hardware event. To capture multiple events, the user manually resets the bit to '1' in software following any Power-on Reset. Alternatively, the VDDPOR (RCON3<2>) bit can be used; it is set on a VDD POR event. It must be cleared after any Power-on Reset to detect subsequent VDD POR events.

After TPWRT expires, an additional start-up time for the system clock (either TOST, TIOBST and TRC, depending on the source) occurs while the clock source becomes stable. Internal Reset is then released and the device is no longer held in Reset (Table 5-2). Once all of the delays have expired, the system clock is released and code execution can begin. Refer to Section 30.0 "Electrical Specifications" for more information on the values of the delay parameters.

Note: When the device exits the Reset condition (begins normal operation), the device operating parameters (voltage, frequency, temperature, etc.) must be within their operating ranges; otherwise, the device will not function correctly. The user must ensure that the delay between the time <u>power is first applied</u>, and the time, INTERNAL RESET, becomes inactive, is long enough to get all operating parameters within specification.

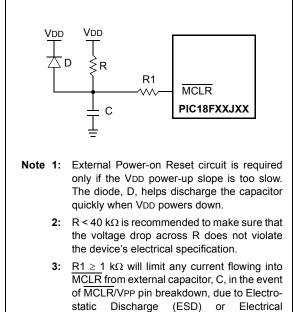

# 5.2.1.1 Using the POR Circuit

To take advantage of the POR circuit, tie the MCLR pin directly to VDD. This will eliminate external RC components usually needed to create a POR delay. A minimum rise time for VDD is required. Refer to the **"Electrical Characteristics"** section of the specific device data sheet for more information.

Depending on the application, a resistor may be required between the MCLR pin and VDD. This resistor can be used to decouple the MCLR pin from a noisy power supply rail.

Figure 5-3 displays a possible POR circuit for a slow power supply ramp up. The external POR circuit is only required if the device would exit Reset before the device VDD is in the valid operating range. The diode, D, helps discharge the capacitor quickly when VDD powers down.

Overstress (EOS).

# 5.2.2 VBAT POWER-ON-RESET (VBPOR)

The device will remain in VBAT mode as long as no power is present on VDD. The VBPOR is active when the device is operating in VBAT mode and deriving power from the VBAT pin. Similar to the POR, the circuit monitors VBAT voltage and holds the device in Reset until adequate voltage is present to power up the device. After exiting the VBAT POR condition, the VBPOR (RCON3<1>) bit is set. All other registers will be in a POR state, including Deep Sleep semaphores. Minimum VBAT ramp time and rearm voltage requirements apply. Refer to Parameters D003 and D004 in **Section 30.0 "Electrical Specifications"** for details.

The device does not execute code in VBAT mode. Also, there is no Power-up Timer associated with VBPOR.

After VDD power is restored, the device exits VBAT mode and the VBAT (RCON3<0>) bit is set. All other registers, except those associated with RTCC, its clock source and the Deep Sleep semaphores (DSGPRx), will be in a POR state. For more information about VBAT mode, see Section 4.5 "Vbat Mode".

# 5.3 Master Clear Reset (MCLR)

Whenever the MCLR pin is driven low, the device asynchronously asserts SYSRST, provided the input pulse on MCLR is longer than a certain minimum width, TMCL (see Section 30.0 "Electrical Specifications"). When the MCLR pin is released, SYSRST is also released. The Reset vector fetch starts from the SYSRST release. The processor continues to use the existing clock source that was in use before the MCLR Reset occurred. The EXTR Status bit (RCON2<7>) is set to indicate the MCLR Reset.

# 5.4 Watchdog Timer Reset (WDT)

Whenever a Watchdog Timer time-out occurs, the device asynchronously asserts SYSRST. The clock source remains unchanged. Note that a WDT time-out during Sleep or Idle mode will wake-up the processor, but NOT reset the processor. The TO bit (RCON<3>) is cleared when a WDT time-out occurs. Software must set this bit to initialize the flag. For more information, refer to Section 28.2 "Watchdog Timer (WDT)".

# 5.5 Configuration Mismatch Reset (CM)

The Configuration Mismatch (CM) Reset is designed to detect, and attempt to recover from, random memory corrupting events. These include Electrostatic Discharge (ESD) events, which can cause widespread, single bit changes throughout the device and result in catastrophic failure.

In PIC18FXXJXX Flash devices, device Configuration registers (located in the configuration memory space) are continuously monitored during operation by comparing their values to complimentary shadow registers. If a mismatch is detected between the two sets of registers, a CM Reset automatically occurs. These events are captured by the  $\overline{CM}$  bit (RCON<5>) being set to '0'.

This bit does not change for any other Reset event. A CM Reset behaves similarly to a Master Clear Reset, RESET instruction, WDT Time-out Reset or Stack Event Reset. As with all hard and power Reset events, the device's Configuration Words are reloaded from the Flash Configuration Words in program memory as the device restarts.

5.6 Brown-out Reset (BOR) Features

The PIC97J94 family has four different types of BOR circuits:

- Brown-out Reset (BOR)
- VDDCORE Brown-out Reset (VDDBOR)
- VBAT Brown-out Reset (VBATBOR)
- Deep Sleep Brown-out Reset (DSBOR)

All four BOR circuits monitor a voltage and put the device in a Reset condition while the voltage is in a specified region. SFRs will reset to the BOR state, including the Deep Sleep semaphore holding registers, DSGPR0 and DSGPR1. Upon BOR exit, the device remains in Reset until the associated trip point voltage is exceeded. Any I/O pins configured as outputs will be tri-stated. BOR, VDDBOR and DSBOR exit into Run mode; VBATBOR remains in VBAT mode.

These features differ by their power mode, monitored voltage source, trip points, control and status. Refer to Table 5-1 for the PIC18F97J94 BOR differences.

Feature	Mode	Source	Trip Points	Enable
BOR	Run, Idle, Sleep	VDDCORE	1.6V (typ)	Always Enabled
VDDBOR	Run, Idle, Sleep	Vdd	VVDDBOR	BOREN (CONFIG1H<0>)
VBATBOR	VBAT	VBAT	VVBATBOR	VBTBOR (CONFIG7L<2>)
DSBOR	Deep Sleep	Vdd	VDSBOR	DSBOREN (CONFIG7L<3>)

TABLE 5-1:BOR FEATURE SUMMARY(1)

Note 1: Refer to Table for details.

# 5.6.1 BROWN-OUT RESET (BOR)

Brown-out Reset is the legacy PIC18 "J" feature that monitors the core voltage, VDDCORE. Since the regulator on the PIC18F97J94 family is always enabled, this feature is always active. Its trip point is non-configurable. A Brown-out Reset will occur as the regulator output voltage drops below, approximately 1.6V. After proper operating voltage recovers, the Brown-out Reset condition is exited and execution begins after the Power-up Timer has expired. The BOR (RCON<0>) bit is also cleared. This bit must be set after each Brown-out and Power-on Reset event to detect subsequent Brown-out Reset events.

Note: Brown-out Reset (BOR) has been provided to support legacy devices that can disable their internal regulator. The PIC18F97J94 family's regulator is always enabled. Therefore, it's recommended that new designs use VDDBOR to detect Brown-out conditions.

# 5.6.2 VDD BOR (VDDBOR)

VDDBOR is enabled by setting the BOREN (CON-FIG1H<0>) Configuration bit. The low-power BOR trip level is configurable to either 1.8V or 2.0V, (typ) depending on the BORV (CONFIG1H<1>) Configuration bit setting. When in normal Run mode, Idle or normal Sleep modes, the BOR circuit that monitors VDD is active and will cause the device to be held in BOR if VDD drops below VBOR. Once VDD rises back above VVDDBOR, the device will be held in Reset until the expiration of the Power-up Timer, with period, TPWRT. This event is captured by the VDDBOR flag bit (RCON3<3>).

### 5.6.3 DETECTING VDD BOR

When the BOR module is enabled, the VDDBOR (RCON3<3>) bit is set on a Brown-out Reset event. This makes it difficult to determine if a Brown-out Reset event has occurred just by reading the state of VDDBOR alone. A more reliable method is to simultaneously check the state of both VDDPOR and VDDBOR. This assumes that the VDDPOR bit is reset to '1' in software immediately after any Power-on Reset event. If VDDBOR is '0' while VDDPOR is '1', it can be reliably assumed that a Brown-out Reset event has occurred. Legacy PIC18 software can use the respective POR (RCON<1>) and BOR (RCON<0>) bits. This technique monitors the regulator output voltage, VDDCORE. To take advantage of the configuration features, it is recommended to use VDDBOR instead of BOR.

### 5.6.4 VBAT BROWN-OUT RESET (VBATBOR)

The VBAT BOR can be enabled/disabled using the VBTBOR bit in the Configuration register (CON-FIG7L<2>). If the VBTBOR enable bit is cleared, the VBATBOR is always disabled and there will be no indication of a VBAT BOR. If the VBTBOR bit is set, the VBAT POR will reset the device when the battery voltage drops below VVBATBOR. After power is restored to the VBAT pin, the device exits Reset and returns to VBAT mode. The device remains in VBAT mode until power returns to the VDD pin. For more information on using the VBAT feature, refer to Section 4.5 "Vbat Mode".

### 5.6.5 DEEP SLEEP BROWN-OUT RESET (DSBOR)

The PIC18F97J94 has its dedicated BOR for Deep Sleep mode (DSBOR). It is enabled through the DSBOREN (CONFIG7L<3>) Configuration bit. When the device enters Deep Sleep mode and receives a DSBOR event, the device will not wake-up and will remain in Deep Sleep mode. When a valid wake-up event occurs and causes the device to exit Deep Sleep mode, software can determine if a DSBOR event occurred during Deep Sleep mode by reading the DSBOR (DSCONL<1>) Status bit.

# 5.7 RESET Instruction

Whenever the <u>RESET</u> instruction is executed, the device asserts SYSRST. This Reset state does not reinitialize the clock. The clock source that is in effect prior to the RESET instruction remains in effect. Configuration settings are updated and the SYSRST is released at the next instruction cycle. A noise filter in the MCLR Reset path detects and ignores small pulses. The RI bit (RCON<4>) is cleared when a RESET instruction is executed. Software must set this bit to initialize the flag.

# 5.8 Stack Underflow/Overflow Reset

A Reset can be enabled on stack error conditions by setting the STVREN (CONFIG1L<5>) Configuration bit. See Section 6.1.4.4 "Stack Full and Underflow Resets" section for additional information.

# 5.9 Device Reset Timers

PIC18F97J94 family devices incorporate three separate on-chip timers that help regulate the Power-on Reset process. Their main function is to ensure that the device clock is stable before code is executed. These timers are:

- Power-up Timer (PWRT)
- Oscillator Start-up Timer (OST)
- PLL Lock Time-out

#### 5.9.1 POWER-UP TIMER (PWRT)

The Power-up Timer (PWRT) of the PIC18F97J94 family devices is a counter which uses the INTOSC source as the clock input. While the PWRT is counting, the device is held in Reset. The power-up time delay depends on the INTOSC clock and varies slightly from chip-to-chip due to temperature and process variation. See the TPWRT specification for details. The PWRT is always enabled and active after Brown-out and Poweron Reset events.

#### 5.9.2 OSCILLATOR START-UP TIMER (OST)

The Oscillator Start-up Timer (OST) provides a 1024 oscillator cycle (from OSC1 input) delay after the PWRT delay is over. This ensures that the crystal oscillator or resonator has started and stabilized.

The OST time-out is invoked only for LP, MS, HS and HSPLL modes, and only on Power-on Reset or on exit from most power-managed modes.

# 5.9.3 PLL LOCK TIME-OUT

The PLL is enabled by programming FOSC<2:0> = 011 (CONFIG2L<2:0>. With the PLL enabled, the time-out sequence, following a Power-on Reset, is slightly different from other oscillator modes. A separate timer is used to provide a fixed time-out that is sufficient for the PLL to lock to the main oscillator frequency. This PLL lock timeout (TRC) follows the oscillator start-up time-out.

### 5.9.4 RESET STATE OF REGISTERS

Most registers are unaffected by a Reset. Their status is unknown on a Power-on Reset and unchanged by all other Resets. The other registers are forced to a "Reset state" depending on the type of Reset that occurred.

Most registers are not affected by a WDT wake-up, since this is viewed as the resumption of normal operation. Status bits from the RCONx registers are set or cleared differently in different Reset situations, as indicated in Table 5-2. These bits are used in software to determine the nature of the Reset.

Table 5-2 describes the Reset states for all of the Special Function Registers. These are categorized by Power-on and Brown-out Resets, Master Clear and WDT Resets, and WDT wake-ups.

#### TABLE 5-2: RCONx BIT OPERATION ON VARIOUS RESETS AND WAKE-UPS

Conditions	РС	dTSdQ	EXTR	RI	<u>10</u>	<u>Od</u>	IDLE	CM	BOR	POR	VDDBOR	VDDPOR	VBPOR <sup>(4,6)</sup>	VBAT <sup>(4)</sup>

IDLE Instruction	PC + 2	u	u	u	0	1	1	u	u	u	u	u	u	u
SLEEP Instruction	PC + 2	u	u	u	0	0	0	u	u	u	u	u	u	u
User Instruction Writes '1'	PC + 2	u	1	1	1	0	1	1	1	1	1	1	1	1
User Instruction Writes '0'	PC + 2	0	0	0	0	1	0	0	0	0	0	0	0	0

Note 1: The  ${\tt SLEEP}$  instruction clears the WDTO bit.

2: The CLRWDT clears the WDTO bit only when the WDT window feature is disabled or the WDT is in the safe window.

3: This bit is also set, flagging the loss of state retention even though the true POR condition has not occurred.

4: This bit is set in hardware only; it can only be cleared in software.

5: Indicates a VDD POR. Setting the POR bit (RCON<0>) indicates a VCORE POR.

6: This bit is set when the device is originally powered up, even if power is present on VBAT.

 TABLE 5-3:
 INITIALIZATION CONDITIONS FOR ALL REGISTERS

**Legend:** u = unchanged; x = unknown; - = unimplemented bit, read as '0'; q = value depends on condition. Shaded cells indicate that conditions do not apply for the designated device.

**Note 1:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

**2:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

- 4: See Table 5-2 for Reset value for specific condition.
- 5: Bits 7,6 are unimplemented on 64 and 80-pin devices.
- 6: If the VBAT is always powered, the DSGPx register values will remain unchanged after the first POR.

TABLE 5-3:	INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

**Legend:** u = unchanged; x = unknown; - = unimplemented bit, read as '0'; q = value depends on condition. Shaded cells indicate that conditions do not apply for the designated device.

**Note 1:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

**2:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

4: See Table 5-2 for Reset value for specific condition.

- 5: Bits 7,6 are unimplemented on 64 and 80-pin devices.
- 6: If the VBAT is always powered, the DSGPx register values will remain unchanged after the first POR.

### TABLE 5-3: INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

**Legend:** u = unchanged; x = unknown; - = unimplemented bit, read as '0'; q = value depends on condition. Shaded cells indicate that conditions do not apply for the designated device.

**Note 1:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

2: When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

- 4: See Table 5-2 for Reset value for specific condition.
- 5: Bits 7,6 are unimplemented on 64 and 80-pin devices.
- 6: If the VBAT is always powered, the DSGPx register values will remain unchanged after the first POR.

#### TABLE 5-3: INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

**Legend:** u = unchanged; x = unknown; - = unimplemented bit, read as '0'; q = value depends on condition. Shaded cells indicate that conditions do not apply for the designated device.

**Note 1:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

**2:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).

3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).

- 4: See Table 5-2 for Reset value for specific condition.
- 5: Bits 7,6 are unimplemented on 64 and 80-pin devices.
- 6: If the VBAT is always powered, the DSGPx register values will remain unchanged after the first POR.

#### TABLE 5-3: INITIALIZATION CONDITIONS FOR ALL REGISTERS (CONTINUED)

**Legend:** u = unchanged; x = unknown; – = unimplemented bit, read as '0'; q = value depends on condition. Shaded cells indicate that conditions do not apply for the designated device.

**Note 1:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the TOSU, TOSH and TOSL are updated with the current value of the PC. The STKPTR is modified to point to the next location in the hardware stack.

- **2:** When the wake-up is due to an interrupt and the GIEL or GIEH bit is set, the PC is loaded with the interrupt vector (0008h or 0018h).
- 3: One or more bits in the INTCONx or PIRx registers will be affected (to cause wake-up).
- 4: See Table 5-2 for Reset value for specific condition.
- 5: Bits 7,6 are unimplemented on 64 and 80-pin devices.
- 6: If the VBAT is always powered, the DSGPx register values will remain unchanged after the first POR.

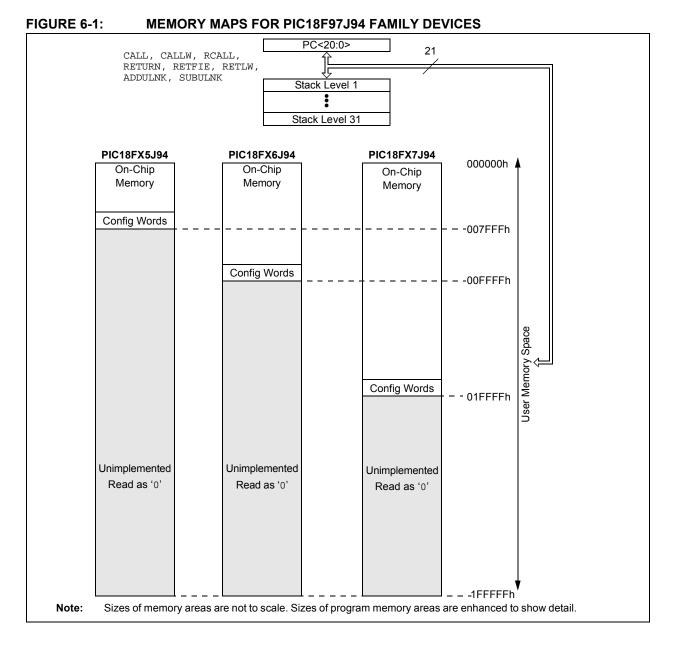

### 6.0 MEMORY ORGANIZATION

PIC18FXXJ94 devices have these types of memory:

- Program Memory
- Data RAM

As Harvard architecture devices, the data and program memories use separate buses. This enables concurrent access of the two memory spaces.

Additional detailed information on the operation of the Flash program memory is provided in **Section 7.0 "Flash Program Memory"**.

#### 6.1 Program Memory Organization

PIC18 microcontrollers implement a 21-bit Program Counter that is capable of addressing a 2-Mbyte program memory space. Accessing a location between the upper boundary of the physically implemented memory and the 2-Mbyte address will return all '0's (a NOP instruction).

The entire PIC18FXXJ94 offers a range of on-chip Flash program memory sizes, from 32 Kbytes (up to 16,384 single-word instructions) to 128 Kbytes (65,536 single-word instructions).

- PIC18F65J94, PIC18F85J94 and PIC18F95J94 32 Kbytes of Flash memory, storing up to 16,384 single-word instructions
- PIC18F66J94, PIC18F86J94 and PIC18F96J94 64 Kbytes of Flash memory, storing up to 32,768 single-word instructions
- PIC18F67J94, PIC18F87J94 and PIC18F97J94 128 Kbytes of Flash memory, storing up to 65,536 single-word instructions

The program memory maps for individual family members are shown in Figure 6-1.

#### 6.1.1 HARD MEMORY VECTORS

All PIC18 devices have a total of three hard-coded return vectors in their program memory space. The Reset vector address is the default value to which the Program Counter returns on all device Resets; it is located at 0000h.

PIC18 devices also have two interrupt vector addresses for handling high-priority and low-priority interrupts. The high-priority interrupt vector is located at 0008h and the low-priority interrupt vector is at 0018h. The locations of these vectors are shown, in relation to the program memory map, in Figure 6-2.

#### 6.1.2 FLASH CONFIGURATION WORDS

Because PIC18FXXJ94 devices do not have persistent configuration memory, the top eight words of on-chip program memory are reserved for configuration information. On Reset, the configuration information is copied into the Configuration registers.

The Configuration Words are stored in their program memory location in numerical order, starting with the lower byte of CONFIG1 at the lowest address and ending with the upper byte of CONFIG8. The actual addresses of the Flash Configuration Word for devices in the PIC18FXXJ94 are shown in Table 6-1.

Their location in the memory map is shown with the other memory vectors in Figure 6-2. Additional details on the device Configuration Words are provided in **Section 28.1 "Configuration Bits"**.

# TABLE 6-1:FLASH CONFIGURATION<br/>WORD FOR PIC18FXXJ94<br/>FAMILY DEVICES

Device	Program Memory (Kbytes)	Configuration Word Addresses
PIC18F65J94 PIC18F85J94 PIC18F95J94	32	7FF0h to 7FFFh
PIC18F66J94 PIC18F86J94 PIC18F96J94	64	FFF0h to FFFFh
PIC18F67J94 PIC18F87J94 PIC18F97J94	128	1FFF0h to 1FFFFh

#### HARD VECTOR FOR PIC18F97J94 FAMILY DEVICES

	Reset Vector	0000h				
	High-Priority Interrupt Vector	0008h				
	Low-Priority Interrupt Vector	0018h				
	On-Chip Program Memory					
	Flash Configuration Words	(Top of Memory-17) (Top of Memory)				
	Read '0'					
		1FFFFFh				
Le	Legend: (Top of Memory) represents upper boundary of on-chip program memory space (see Figure 6-1 for device-specific values). Shaded area represents unimplemented memory. Areas are not shown to scale.					

#### 6.1.3 **PROGRAM COUNTER**

The Program Counter (PC) specifies the address of the instruction to fetch for execution. The PC is 21 bits wide and contained in three separate 8-bit registers.

The low byte, known as the PCL register, is both readable and writable. The high byte, or PCH register, contains the PC<15:8> bits and is not directly readable or writable. Updates to the PCH register are performed through the PCLATH register. The upper byte is called PCU. This register contains the PC<20:16> bits; it is also not directly readable or writable. Updates to the PCU register are performed through the PCLATU register.

The contents of PCLATH and PCLATU are transferred to the Program Counter by any operation that writes PCL. Similarly, the upper two bytes of the Program Counter are transferred to PCLATH and PCLATU by an operation that reads PCL. This is useful for computed offsets to the PC (see Section 6.1.6.1 "Computed GOTO").

The PC addresses bytes in the program memory. To prevent the PC from becoming misaligned with word instructions, the Least Significant bit of PCL is fixed to a value of '0'. The PC increments by two to address sequential instructions in the program memory.

The CALL, RCALL, GOTO and program branch instructions write to the Program Counter directly. For these instructions, the contents of PCLATH and PCLATU are not transferred to the Program Counter.

#### 6.1.4 RETURN ADDRESS STACK

The return address stack enables execution of any combination of up to 31 program calls and interrupts. The PC is pushed onto the stack when a CALL or RCALL instruction is executed or an interrupt is Acknowledged. The PC value is pulled off the stack on a RETURN, RETLW or a RETFIE instruction. The value also is pulled off the stack on ADDULNK and SUBULNK instructions, if the extended instruction set is enabled. PCLATU and PCLATH are not affected by any of the RETURN or CALL instructions.

The stack operates as a 31-word by 21-bit RAM and a 5-bit Stack Pointer, STKPTR. The stack space is not part of either program or data space. The Stack Pointer is readable and writable and the address on the top of the stack is readable and writable through the Top-of-Stack Special Function Registers. Data can also be pushed to, or popped from, the stack using these registers.

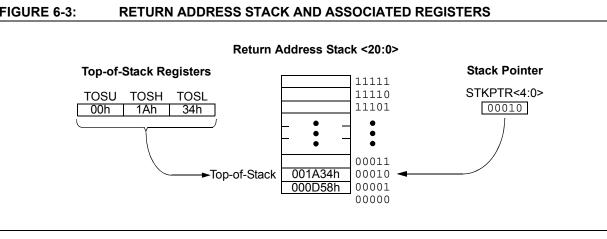

A CALL type instruction causes a push onto the stack. The Stack Pointer is first incremented and the location pointed to by the Stack Pointer is written with the contents of the PC (already pointing to the instruction following the CALL). A RETURN type instruction causes a pop from the stack. The contents of the location pointed to by the STKPTR are transferred to the PC and then the Stack Pointer is decremented.

The Stack Pointer is initialized to '00000' after all Resets. There is no RAM associated with the location corresponding to a Stack Pointer value of '00000'; this is only a Reset value. Status bits indicate if the stack is full, has overflowed or has underflowed.

#### 6.1.4.1 **Top-of-Stack Access**

Only the top of the return address stack (TOS) is readable and writable. A set of three registers, TOSU:TOSH:TOSL, holds the contents of the stack location pointed to by the STKPTR register (Figure 6-3). This allows users to implement a software stack, if necessary. After a CALL, RCALL or interrupt (or ADDULNK and SUBULNK instructions, if the extended instruction set is enabled), the software can read the pushed value by reading the TOSU:TOSH:TOSL registers. These values can be placed on a user-defined software stack. At return time, the software can return these values to TOSU:TOSH:TOSL and do a return.

While accessing the stack, users must disable the Global Interrupt Enable bits to prevent inadvertent stack corruption.

#### FIGURE 6-3:

#### 6.1.4.2 Return Stack Pointer (STKPTR)

The STKPTR register (Register 6-1) contains the Stack Pointer value, the STKFUL (Stack Full) Status bit and the STKUNF (Stack Underflow) Status bits. The value of the Stack Pointer can be 0 through 31. The Stack Pointer increments before values are pushed onto the stack and decrements after values are popped off the stack. On Reset, the Stack Pointer value will be zero.

The user may read and write the Stack Pointer value. This feature can be used by a Real-Time Operating System (RTOS) for return-stack maintenance.

After the PC is pushed onto the stack, 31 times (without popping any values off the stack), the STKFUL bit is set. The STKFUL bit is cleared by software or by a POR.

What happens when the stack becomes full depends on the state of the STVREN (Stack Overflow Reset Enable) Configuration bit. (For a description of the device Configuration bits, see **Section 28.1 "Configuration Bits"**.) If STVREN is set (default), the 31st push will push the (PC + 2) value onto the stack, set the STKFUL bit and reset the device. The STKFUL bit will remain set and the Stack Pointer will be set to zero.

If STVREN is cleared, the STKFUL bit will be set on the 31st push and the Stack Pointer will increment to 31. Any additional pushes will not overwrite the 31st push and the STKPTR will remain at 31.

When the stack has been popped enough times to unload the stack, the next pop will return a value of zero to the PC and set the STKUNF bit, while the Stack Pointer remains at zero. The STKUNF bit will remain set until cleared by software or until a POR occurs.

Note:	Returning a value of zero to the PC on an underflow has the effect of vectoring the
	program to the Reset vector, where the
	stack conditions can be verified and
	appropriate actions can be taken. This is
	not the same as a Reset, as the contents
	of the SFRs are not affected.

#### 6.1.4.3 PUSH and POP Instructions

Since the Top-of-Stack is readable and writable, the ability to push values onto the stack and pull values off the stack, without disturbing normal program execution, is a desirable feature. The PIC18 instruction set includes two instructions, PUSH and POP, that permit the TOS to be manipulated under software control. TOSU, TOSH and TOSL can be modified to place data or a return address on the stack.

The PUSH instruction places the current PC value onto the stack. This increments the Stack Pointer and loads the current PC value onto the stack.

The POP instruction discards the current TOS by decrementing the Stack Pointer. The previous value pushed onto the stack then becomes the TOS value.

#### R/C-0 R/C-0 R/W-0 U-0 R/W-0 R/W-0 R/W-0 R/W-0 STKFUL<sup>(1)</sup> STKUNF<sup>(1)</sup> SP4 SP3 SP2 SP1 SP0 bit 7 bit 0 Legend: C = Clearable bit R = Readable bit W = Writable bit U = Unimplemented bit, read as '0' '0' = Bit is cleared -n = Value at POR '1' = Bit is set x = Bit is unknown STKFUL: Stack Full Flag bit<sup>(1)</sup> bit 7 1 = Stack has become full or overflowed 0 = Stack has not become full or overflowed STKUNF: Stack Underflow Flag bit<sup>(1)</sup> bit 6 1 = Stack underflow has occurred 0 = Stack underflow did not occur

bit 4-0

#### 6.1.4.4 Stack Full and Underflow Resets

Device Resets on stack overflow and stack underflow conditions are enabled by setting the STVREN bit (CONFIG1L<5>). When STVREN is set, a full or underflow condition will set the appropriate STKFUL or STKUNF bit and then cause a device Reset. When STVREN is cleared, a full or underflow condition will set the appropriate STKFUL or STKUNF bit, but not cause a device Reset. The STKFUL or STKUNF bits are cleared by user software or a Power-on Reset.

#### 6.1.5 FAST REGISTER STACK

A Fast Register Stack is provided for the STATUS, WREG and BSR registers to provide a "fast return" option for interrupts. This stack is only one level deep and is neither readable nor writable. It is loaded with the current value of the corresponding register when the processor vectors for an interrupt. All interrupt sources will push values into the Stack registers. The values in the registers are then loaded back into the working registers if the RETFIE, FAST instruction is used to return from the interrupt.

If both low and high-priority interrupts are enabled, the Stack registers cannot be used reliably to return from low-priority interrupts. If a high-priority interrupt occurs while servicing a low-priority interrupt, the Stack register values stored by the low-priority interrupt will be overwritten. In these cases, users must save the key registers in software during a low-priority interrupt.

If interrupt priority is not used, all interrupts may use the Fast Register Stack for returns from interrupt. If no interrupts are used, the Fast Register Stack can be used to restore the STATUS, WREG and BSR registers at the end of a subroutine call. To use the Fast Register Stack for a subroutine call, a CALL label, FAST instruction must be executed to save the STATUS, WREG and BSR registers to the Fast Register Stack. A RETURN, FAST instruction is then executed to restore these registers from the Fast Register Stack.

Example 6-1 shows a source code example that uses the Fast Register Stack during a subroutine call and return.

#### EXAMPLE 6-1: FAST REGISTER STACK CODE EXAMPLE

CALL SUB1, FAST	;STATUS, WREG, BSR
•	;SAVED IN FAST REGISTER
SUB1 •	;STACK
RETURN FAST	;RESTORE VALUES SAVED ;IN FAST REGISTER STACK

#### 6.1.6 LOOK-UP TABLES IN PROGRAM MEMORY

There may be programming situations that require the creation of data structures, or look-up tables, in program memory. For PIC18 devices, look-up tables can be implemented in two ways:

- Computed GOTO
- Table Reads

#### 6.1.6.1 Computed GOTO

A computed GOTO is accomplished by adding an offset to the Program Counter. An example is shown in Example 6-2.

A look-up table can be formed with an ADDWF PCL instruction and a group of RETLW nn instructions. The W register is loaded with an offset into the table before executing a call to that table. The first instruction of the called routine is the ADDWF PCL instruction. The next instruction executed will be one of the RETLW nn instructions that returns the value, 'nn', to the calling function.

The offset value (in WREG) specifies the number of bytes that the Program Counter should advance and should be multiples of two (LSb = 0).

In this method, only one data byte may be stored in each instruction location and room on the return address stack is required.

#### EXAMPLE 6-2: COMPUTED GOTO USING AN OFFSET VALUE

	MOVF	OFFSET, W
	CALL	TABLE
ORG	nn00h	
TABLE	ADDWF	PCL
	RETLW	nnh
	RETLW	nnh
	RETLW	nnh

#### 6.1.6.2 Table Reads

A better method of storing data in program memory allows two bytes of data to be stored in each instruction location.

Look-up table data may be stored, two bytes per program word, while programming. The Table Pointer (TBLPTR) specifies the byte address and the Table Latch (TABLAT) contains the data that is read from the program memory. Data is transferred from program memory one byte at a time.

The table read operation is discussed further in **Section 7.1 "Table Reads and Table Writes**".

#### 6.2 PIC18 Instruction Cycle

#### 6.2.1 CLOCKING SCHEME

The microcontroller clock input, whether from an internal or external source, is internally divided by four to generate four non-overlapping quadrature clocks (Q1, Q2, Q3 and Q4). Internally, the Program Counter is incremented on every Q1, with the instruction fetched from the program memory and latched into the Instruction Register (IR) during Q4.

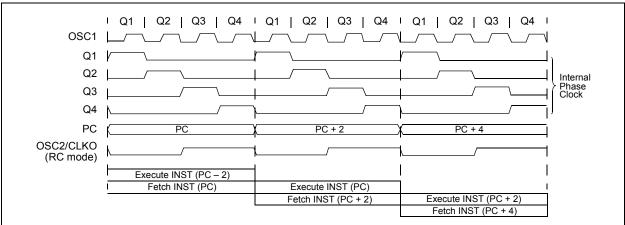

The instruction is decoded and executed during the following Q1 through Q4. The clocks and instruction execution flow are shown in Figure 6-4.

#### 6.2.2 INSTRUCTION FLOW/PIPELINING

An "Instruction Cycle" consists of four Q cycles, Q1 through Q4. The instruction fetch and execute are pipelined in such a manner that a fetch takes one instruction cycle, while the decode and execute take another instruction cycle. However, due to the pipelining, each instruction effectively executes in one cycle. If an instruction (such as GOTO) causes the Program Counter to change, two cycles are required to complete the instruction. (See Example 6-3.)

A fetch cycle begins with the Program Counter (PC) incrementing in Q1.

In the execution cycle, the fetched instruction is latched into the Instruction Register (IR) in cycle Q1. This instruction is then decoded and executed during the Q2, Q3 and Q4 cycles. Data memory is read during Q2 (operand read) and written during Q4 (destination write).

#### FIGURE 6-4: CLOCK/INSTRUCTION CYCLE

#### EXAMPLE 6-3: INSTRUCTION PIPELINE FLOW

Tcy0	TCY1	TCY2	TCY3	TCY4	TCY5
1. MOVLW 55h Fetch 1	Execute 1				
2. MOVWF PORTB	Fetch 2	Execute 2		_	
3. BRA SUB_1		Fetch 3	Execute 3		
4. BSF PORTA, BIT3 (Forced NOP)			Fetch 4	Flush (NOP)	
5. Instruction @ address SUB_1				Fetch SUB_1	Execute SUB_1

All instructions are single cycle, except for any program branches. These take two cycles since the fetch instruction is "flushed" from the pipeline while the new instruction is being fetched and then executed.

#### 6.2.3 INSTRUCTIONS IN PROGRAM MEMORY

The program memory is addressed in bytes. Instructions are stored as two or four bytes in program memory. The Least Significant Byte of an instruction word is always stored in a program memory location with an even address (LSB = 0). To maintain alignment with instruction boundaries, the PC increments in steps of two and the LSB will always read '0' (see Section 6.1.3 "Program Counter").

Figure 6-5 shows an example of how instruction words are stored in the program memory.

The CALL and GOTO instructions have the absolute program memory address embedded into the instruction. Since instructions are always stored on word boundaries, the data contained in the instruction is a word address. The word address is written to PC<20:1> which accesses the desired byte address in program memory. Instruction #2 in Figure 6-5 shows how the instruction, GOTO 0006h, is encoded in the program memory. Program branch instructions, which encode a relative address offset, operate in the same manner. The offset value stored in a branch instruction represents the number of single-word instructions that the PC will be offset by. For more details on the instruction set, see **Section 29.0 "Instruction Set Summary"**.

#### 6.2.4 TWO-WORD INSTRUCTIONS

The standard PIC18 instruction set has four, two-word instructions: CALL, MOVFF, GOTO and LSFR. In all cases, the second word of the instructions always has '1111' as its four Most Significant bits. The other 12 bits are literal data, usually a data memory address.

The use of '1111' in the 4 MSbs of an instruction specifies a special form of NOP. If the instruction is executed in proper sequence, immediately after the first word, the data in the second word is accessed and

used by the instruction sequence. If the first word is skipped, for some reason, and the second word is executed by itself, a NOP is executed instead. This is necessary for cases when the two-word instruction is preceded by a conditional instruction that changes the PC. Example 6-4 shows how this works.

Note: For information on two-word instructions in the extended instruction set, see Section 6.5 "Program Memory and the Extended Instruction Set".

EXAMPLE 6-4:	TWO-WORD INSTRUCTIONS

#### 6.3 Data Memory Organization

Note:	The operation of some aspects of data							
	memory are changed when the PIC18							
	extended instruction set is enabled. See							
	Section 6.6 "Data Memory and the							
	Extended Instruction Set" for more							
	information.							

The data memory in PIC18 devices is implemented as static RAM. Each register in the data memory has a 12bit address, allowing up to 4,096 bytes of data memory. The memory space is divided into as many as 16 banks that contain 256 bytes each. PIC18FXXJ94 devices implement all 16 banks, for a total of 4 Kbytes.

Figure 6-6 and Figure 6-7 show the data memory organization for the devices.

The data memory contains Special Function Registers (SFRs) and General Purpose Registers (GPRs). The SFRs are used for control and status of the controller and peripheral functions, while GPRs are used for data storage and scratchpad operations in the user's application. Any read of an unimplemented location will read as '0's.

The instruction set and architecture allow operations across all banks. The entire data memory may be accessed by Direct, Indirect or Indexed Addressing modes. Addressing modes are discussed later in this section.

To ensure that commonly used registers (select SFRs and select GPRs) can be accessed in a single cycle, PIC18 devices implement an Access Bank. This is a 256-byte memory space that provides fast access to select SFRs and the lower portion of GPR Bank 0 without using the Bank Select Register. For details on the Access RAM, see Section 6.3.2 "Access Bank".

#### 6.3.1 BANK SELECT REGISTER

Large areas of data memory require an efficient addressing scheme to make it possible for rapid access to any address. Ideally, this means that an entire address does not need to be provided for each read or write operation. For PIC18 devices, this is accomplished with a RAM banking scheme. This divides the memory space into 16 contiguous banks of 256 bytes. Depending on the instruction, each location can be addressed directly by its full 12-bit address, or an 8-bit, low-order address and a four-bit Bank Pointer.

Most instructions in the PIC18 instruction set make use of the Bank Pointer, known as the Bank Select Register (BSR). This SFR holds the four Most Significant bits of a location's address. The instruction itself includes the eight Least Significant bits. Only the four lower bits of the BSR are implemented (BSR<3:0>). The upper four bits are unused, always read as '0' and cannot be written to. The BSR can be loaded directly by using the MOVLB instruction.

The value of the BSR indicates the bank in data memory. The eight bits in the instruction show the location in the bank and can be thought of as an offset from the bank's lower boundary. The relationship between the BSR's value and the bank division in data memory is shown in Figure 6-7.

Since up to 16 registers may share the same low-order address, the user must always be careful to ensure that the proper bank is selected before performing a data read or write. For example, writing what should be program data to an 8-bit address of F9h, while the BSR is 0Fh, will end up resetting the Program Counter.

While any bank can be selected, only those banks that are actually implemented can be read or written to. Writes to unimplemented banks are ignored, while reads from unimplemented banks will return '0's. Even so, the STATUS register will still be affected as if the operation was successful. The data memory map in Figure 6-6 indicates which banks are implemented.

In the core PIC18 instruction set, only the MOVFF instruction fully specifies the 12-bit address of the source and target registers. When this instruction executes, it ignores the BSR completely. All other instructions include only the low-order address as an operand and must use either the BSR or the Access Bank to locate their target registers.

The BSR specifies the bank

used by the instruction.

### PIC18F97J94 FAMILY

#### FIGURE 6-7: USE OF THE BANK SELECT REGISTER (DIRECT ADDRESSING)

#### 6.3.2 ACCESS BANK

While the use of the BSR, with an embedded 8-bit address, allows users to address the entire range of data memory, it also means that the user must ensure that the correct bank is selected. If not, data may be read from, or written to, the wrong location. This can be disastrous if a GPR is the intended target of an operation, but an SFR is written to instead. Verifying and/or changing the BSR for each read or write to data memory can become very inefficient.

To streamline access for the most commonly used data memory locations, the data memory is configured with an Access Bank, which allows users to access a mapped block of memory without specifying a BSR. The Access Bank consists of the first 96 bytes of memory (00h-5Fh) in Bank 0 and the last 160 bytes of memory (60h-FFh) in Bank 15. The lower half is known as the "Access RAM" and is composed of GPRs. The upper half is where the device's SFRs are mapped. These two areas are mapped contiguously in the Access Bank and can be addressed in a linear fashion by an 8-bit address (Figure 6-6).

The Access Bank is used by core PIC18 instructions that include the Access RAM bit (the 'a' parameter in the instruction). When 'a' is equal to '1', the instruction uses the BSR and the 8-bit address included in the opcode for the data memory address. When 'a' is '0', however, the instruction is forced to use the Access Bank address map. In that case, the current value of the BSR is ignored entirely.

Using this "forced" addressing allows the instruction to operate on a data address in a single cycle without updating the BSR first. For 8-bit addresses of 60h and above, this means that users can evaluate and operate on SFRs more efficiently. The Access RAM below 60h is a good place for data values that the user might need to access rapidly, such as immediate computational results or common program variables.

Access RAM also allows for faster and more code efficient context saving and switching of variables.

The mapping of the Access Bank is slightly different when the extended instruction set is enabled (XINST Configuration bit = 1). This is discussed in more detail in Section 6.6.3 "Mapping the Access Bank in Indexed Literal Offset Mode".

#### 6.3.3 GENERAL PURPOSE REGISTER FILE

PIC18 devices may have banked memory in the GPR area. This is data RAM which is available for use by all instructions. GPRs start at the bottom of Bank 0 (address 000h) and grow upwards towards the bottom of the SFR area. GPRs are not initialized by a Power-on Reset and are unchanged on all other Resets.

#### 6.3.4 SPECIAL FUNCTION REGISTERS

The Special Function Registers (SFRs) are registers used by the CPU and peripheral modules for controlling the desired operation of the device. These registers are implemented as static RAM. SFRs start at the top of data memory (FFFh) and extend downward to occupy all of Bank 15 (F00h to FFFh), Bank 14 (E00h to EFFh) and part of Bank 13 (DFAh to DFFh).

A list of these registers is given in Table 6-2.

The SFRs can be classified into two sets: those associated with the "core" device functionality (ALU, Resets and interrupts) and those related to the peripheral functions. The Reset and Interrupt registers are described in their respective chapters, while the ALU's STATUS register is described later in this section. Registers related to the operation of the peripheral features are described in the chapter for that peripheral.

The SFRs are typically distributed among the peripherals whose functions they control. Unused SFR locations are unimplemented and read as '0's.

#### 6.3.5 STATUS REGISTER

The STATUS register, shown in Register 6-2, contains the arithmetic status of the ALU. The STATUS register can be the operand for any instruction, as with any other register. If the STATUS register is the destination for an instruction that affects the Z, DC, C, OV or N bits, the write to these five bits is disabled.

These bits are set or cleared according to the device logic. Therefore, the result of an instruction with the STATUS register as destination may be different than intended. For example, CLRF STATUS will set the Z bit but leave the other bits unchanged. The STATUS register then reads back as '000u uluu'.

It is recommended, therefore, that only BCF, BSF, SWAPF, MOVFF and MOVWF instructions be used to alter the STATUS register because these instructions do not affect the Z, C, DC, OV or N bits in the STATUS register.

For other instructions not affecting any Status bits, see the instruction set summaries in Table 29-2 and Table 29-3.

Note: The <u>C</u> and <u>DC</u> bits operate, in subtraction, as borrow and digit borrow bits, respectively.

### REGISTER 6-2: STATUS REGISTER

#### 6.4 Data Addressing Modes

Note:	The execution of some instructions in the
	core PIC18 instruction set are changed
	when the PIC18 extended instruction set is
	enabled. For more information, see
	Section 6.6 "Data Memory and the
	Extended Instruction Set"

While the program memory can be addressed in only one way, through the Program Counter, information in the data memory space can be addressed in several ways. For most instructions, the addressing mode is fixed. Other instructions may use up to three modes, depending on which operands are used and whether or not the extended instruction set is enabled.

The addressing modes are:

- Inherent
- Literal
- Direct
- Indirect

An additional addressing mode, Indexed Literal Offset, is available when the extended instruction set is enabled (XINST Configuration bit = 1). For details on this mode's operation, see Section 6.6.1 "Indexed Addressing with Literal Offset".

### 6.4.1 INHERENT AND LITERAL ADDRESSING

Many PIC18 control instructions do not need any argument at all. They either perform an operation that globally affects the device or they operate implicitly on one register. This addressing mode is known as Inherent Addressing. Examples of this mode include SLEEP, RESET and DAW.

Other instructions work in a similar way, but require an additional explicit argument in the opcode. This method is known as the Literal Addressing mode because the instructions require some literal value as an argument. Examples of this include ADDLW and MOVLW which, respectively, add or move a literal value to the W register. Other examples include CALL and GOTO, which include a 20-bit program memory address.

#### 6.4.2 DIRECT ADDRESSING

Direct Addressing specifies all or part of the source and/or destination address of the operation within the opcode itself. The options are specified by the arguments accompanying the instruction.

In the core PIC18 instruction set, bit-oriented and byteoriented instructions use some version of Direct Addressing by default. All of these instructions include some 8-bit literal address as their Least Significant Byte. This address specifies the instruction's data source as either a register address in one of the banks of data RAM (see Section 6.3.3 "General Purpose Register File") or a location in the Access Bank (see Section 6.3.2 "Access Bank").

The Access RAM bit, 'a', determines how the address is interpreted. When 'a' is '1', the contents of the BSR (Section 6.3.1 "Bank Select Register") are used with the address to determine the complete 12-bit address of the register. When 'a' is '0', the address is interpreted as being a register in the Access Bank. Addressing that uses the Access RAM is sometimes also known as Direct Forced Addressing mode.

A few instructions, such as MOVFF, include the entire 12-bit address (either source or destination) in their opcodes. In these cases, the BSR is ignored entirely.

The destination of the operation's results is determined by the destination bit, 'd'. When 'd' is '1', the results are stored back in the source register, overwriting its original contents. When 'd' is '0', the results are stored in the W register. Instructions without the 'd' argument have a destination that is implicit in the instruction, either the target register being operated on or the W register.

#### 6.4.3 INDIRECT ADDRESSING

Indirect Addressing allows the user to access a location in data memory without giving a fixed address in the instruction. This is done by using File Select Registers (FSRs) as pointers to the locations to be read or written to. Since the FSRs are themselves located in RAM as Special Function Registers, they can also be directly manipulated under program control. This makes FSRs very useful in implementing data structures such as tables and arrays in data memory.

The registers for Indirect Addressing are also implemented with Indirect File Operands (INDFs) that permit automatic manipulation of the pointer value with auto-incrementing, auto-decrementing or offsetting with another value. This allows for efficient code using loops, such as the example of clearing an entire RAM bank in Example 6-5. It also enables users to perform Indexed Addressing and other Stack Pointer operations for program memory in data memory.

#### EXAMPLE 6-5: HOW TO CLEAR RAM (BANK 1) USING INDIRECT ADDRESSING

	LFSR	FSR0, 100h	;	
NEXT	CLRF	POSTINC0	;	Clear INDF
			;	register then
			;	inc pointer
	BTFSS	FSROH, 1	;	All done with
			;	Bank1?
	BRA	NEXT	;	NO, clear next
CONTINU	UE		;	YES, continue

### 6.4.3.1 FSR Registers and the INDF Operand

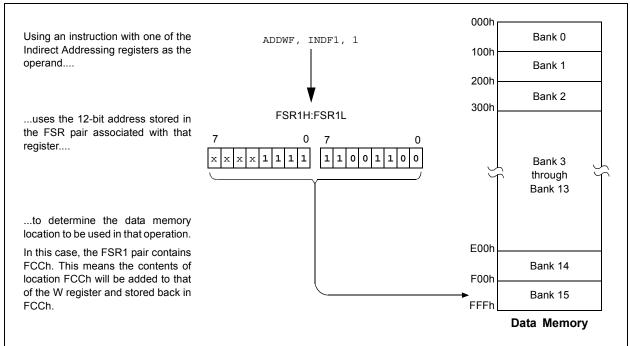

At the core of Indirect Addressing are three sets of registers: FSR0, FSR1 and FSR2. Each represents a pair of 8-bit registers: FSRnH and FSRnL. The four upper bits of the FSRnH register are not used, so each FSR pair holds a 12-bit value. This represents a value that can address the entire range of the data memory in a linear fashion. The FSR register pairs, then, serve as pointers to data memory locations.

Indirect Addressing is accomplished with a set of Indirect File Operands, INDF0 through INDF2. These can be thought of as "virtual" registers. The operands are

#### mapped in the SFR space, but are not physically implemented. Reading or writing to a particular INDF register actually accesses its corresponding FSR register pair. A read from INDF1, for example, reads the data at the address indicated by FSR1H:FSR1L.

Instructions that use the INDF registers as operands actually use the contents of their corresponding FSR as a pointer to the instruction's target. The INDF operand is just a convenient way of using the pointer.

Because Indirect Addressing uses a full 12-bit address, data RAM banking is not necessary. Thus, the current contents of the BSR and the Access RAM bit have no effect on determining the target address.

#### FIGURE 6-8: INDIRECT ADDRESSING

#### 6.4.3.2 FSR Registers and POSTINC, POSTDEC, PREINC and PLUSW

In addition to the INDF operand, each FSR register pair also has four additional indirect operands. Like INDF, these are "virtual" registers that cannot be indirectly read or written to. Accessing these registers actually accesses the associated FSR register pair, but also performs a specific action on its stored value.

These operands are:

- POSTDEC Accesses the FSR value, then automatically decrements it by '1' afterwards
- POSTINC Accesses the FSR value, then automatically increments it by '1' afterwards
- PREINC Increments the FSR value by '1', then uses it in the operation
- PLUSW Adds the signed value of the W register (range of -127 to 128) to that of the FSR and uses the new value in the operation

In this context, accessing an INDF register uses the value in the FSR registers without changing them. Similarly, accessing a PLUSW register gives the FSR value, offset by the value in the W register, with neither value actually changed in the operation. Accessing the other virtual registers changes the value of the FSR registers.

Operations on the FSRs with POSTDEC, POSTINC and PREINC affect the entire register pair. Rollovers of the FSRnL register, from FFh to 00h, carry over to the FSRnH register. On the other hand, results of these operations do not change the value of any flags in the STATUS register (for example, Z, N and OV bits).

The PLUSW register can be used to implement a form of Indexed Addressing in the data memory space. By manipulating the value in the W register, users can reach addresses that are fixed offsets from pointer addresses. In some applications, this can be used to implement some powerful program control structure, such as software stacks, inside of data memory.

#### 6.4.3.3 Operations by FSRs on FSRs

Indirect Addressing operations that target other FSRs or virtual registers represent special cases. For example, using an FSR to point to one of the virtual registers will not result in successful operations.

As a specific case, assume that the FSR0H:FSR0L registers contain FE7h, the address of INDF1. Attempts to read the value of the INDF1, using INDF0 as an operand, will return 00h. Attempts to write to INDF1, using INDF0 as the operand, will result in a NOP.

On the other hand, using the virtual registers to write to an FSR pair may not occur as planned. In these cases, the value will be written to the FSR pair, but without any incrementing or decrementing. Thus, writing to INDF2 or POSTDEC2 will write the same value to the FSR2H:FSR2L.

Since the FSRs are physical registers mapped in the SFR space, they can be manipulated through all direct operations. Users should proceed cautiously when working on these registers, however, particularly if their code uses Indirect Addressing.

Similarly, operations by Indirect Addressing are generally permitted on all other SFRs. Users should exercise the appropriate caution, so that they do not inadvertently change settings that might affect the operation of the device.

### 6.5 Program Memory and the Extended Instruction Set

The operation of program memory is unaffected by the use of the extended instruction set.

Enabling the extended instruction set adds five additional two-word commands to the existing PIC18 instruction set: ADDFSR, CALLW, MOVSF, MOVSS and SUBFSR. These instructions are executed as described in Section 6.2.4 "Two-Word Instructions".

### 6.6 Data Memory and the Extended Instruction Set

Enabling the PIC18 extended instruction set (XINST Configuration bit = 1) significantly changes certain aspects of data memory and its addressing. Using the Access Bank for many of the core PIC18 instructions introduces a new addressing mode for the data memory space. This mode also alters the behavior of Indirect Addressing using FSR2 and its associated operands.

What does not change is just as important. The size of the data memory space is unchanged, as well as its linear addressing. The SFR map remains the same. Core PIC18 instructions can still operate in both Direct and Indirect Addressing mode. Inherent and literal instructions do not change at all. Indirect Addressing with FSR0 and FSR1 also remains unchanged.

### 6.6.1 INDEXED ADDRESSING WITH LITERAL OFFSET

Enabling the PIC18 extended instruction set changes the behavior of Indirect Addressing using the FSR2 register pair and its associated file operands. Under the proper conditions, instructions that use the Access Bank – that is, most bit-oriented and byte-oriented instructions – can invoke a form of Indexed Addressing using an offset specified in the instruction. This special addressing mode is known as Indexed Addressing with Literal Offset or the Indexed Literal Offset mode.

When using the extended instruction set, this addressing mode requires the following:

- Use of the Access Bank ('a' = 0)
- A file address argument that is less than or equal to 5Fh

Under these conditions, the file address of the instruction is not interpreted as the lower byte of an address (used with the BSR in Direct Addressing) or as an 8-bit address in the Access Bank. Instead, the value is interpreted as an offset value to an Address Pointer specified by FSR2. The offset and the contents of FSR2 are added to obtain the target address of the operation.

#### 6.6.2 INSTRUCTIONS AFFECTED BY INDEXED LITERAL OFFSET MODE

Any of the core PIC18 instructions that can use Direct Addressing are potentially affected by the Indexed Literal Offset Addressing mode. This includes all byteoriented and bit-oriented instructions, or almost onehalf of the standard PIC18 instruction set. Instructions that only use Inherent or Literal Addressing modes are unaffected.

Additionally, byte-oriented and bit-oriented instructions are not affected if they do not use the Access Bank (Access RAM bit = 1), or include a file address of 60h or above. Instructions meeting these criteria will continue to execute as before. A comparison of the different possible addressing modes when the extended instruction set is enabled is shown in Figure 6-9.

Those who desire to use byte-oriented or bit-oriented instructions in the Indexed Literal Offset mode should note the changes to assembler syntax for this mode. This is described in more detail in Section 29.2.1 "Extended Instruction Syntax".

### PIC18F97J94 FAMILY

#### FIGURE 6-9: COMPARING ADDRESSING OPTIONS FOR BIT-ORIENTED AND BYTE-ORIENTED INSTRUCTIONS (EXTENDED INSTRUCTION SET ENABLED)

#### **EXAMPLE INSTRUCTION:** ADDWF, f, d, a (Opcode: 0010 01da ffff ffff)

#### When a = 0 and $f \ge 60h$ :

The instruction executes in Direct Forced mode. 'f' is interpreted as a location in the Access RAM between 060h and FFFh. This is the same as locations, F60h to FFFh (Bank 15), of data memory.

Locations below 060h are not available in this addressing mode.

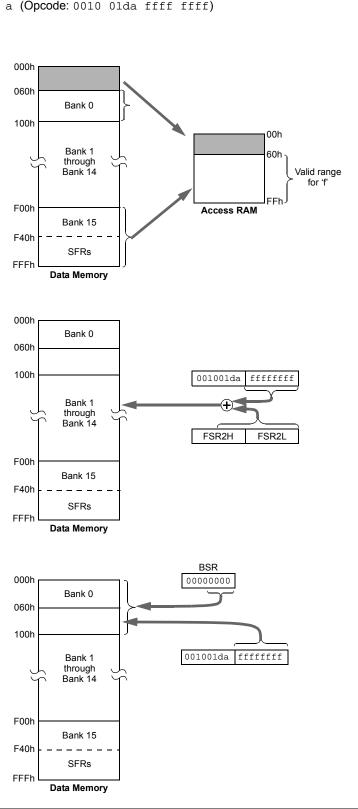

#### When a = 0 and $f \le 5Fh$ :

The instruction executes in Indexed Literal Offset mode. 'f' is interpreted as an offset to the address value in FSR2. The two are added together to obtain the address of the target register for the instruction. The address can be anywhere in the data memory space.

Note that in this mode, the correct syntax is now: ADDWF [k], d where 'k' is the same as 'f'.

#### When a = 1 (all values of f):

The instruction executes in Direct mode (also known as Direct Long mode). 'f' is interpreted as a location in one of the 16 banks of the data memory space. The bank is designated by the Bank Select Register (BSR). The address can be in any implemented bank in the data memory space.

### 6.6.3 MAPPING THE ACCESS BANK IN INDEXED LITERAL OFFSET MODE

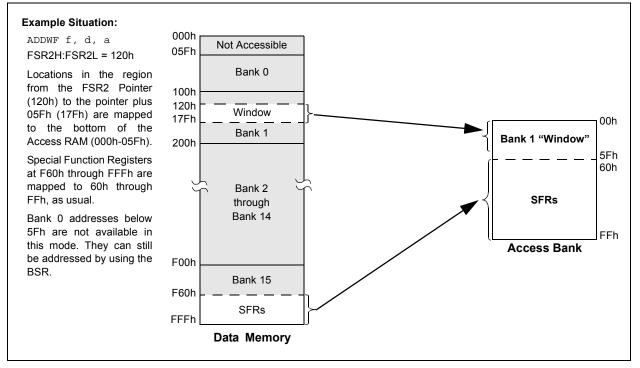

The use of Indexed Literal Offset Addressing mode effectively changes how the lower part of Access RAM (00h to 5Fh) is mapped. Rather than containing just the contents of the bottom part of Bank 0, this mode maps the contents from Bank 0 and a user-defined "window" that can be located anywhere in the data memory space.

The value of FSR2 establishes the lower boundary of the addresses mapped into the window, while the upper boundary is defined by FSR2 plus 95 (5Fh). Addresses in the Access RAM above 5Fh are mapped as previously described. (See **Section 6.3.2 "Access Bank**".) An example of Access Bank remapping in this addressing mode is shown in Figure 6-10. Remapping the Access Bank applies *only* to operations using the Indexed Literal Offset mode. Operations that use the BSR (Access RAM bit = 1) will continue to use Direct Addressing as before. Any Indirect or Indexed Addressing operation that explicitly uses any of the indirect file operands (including FSR2) will continue to operate as standard Indirect Addressing. Any instruction that uses the Access Bank, but includes a register address of greater than 05Fh, will use Direct Addressing and the normal Access Bank map.

#### 6.6.4 BSR IN INDEXED LITERAL OFFSET MODE

Although the Access Bank is remapped when the extended instruction set is enabled, the operation of the BSR remains unchanged. Direct Addressing, using the BSR to select the data memory bank, operates in the same manner as previously described.

### FIGURE 6-10: REMAPPING THE ACCESS BANK WITH INDEXED LITERAL OFFSET ADDRESSING

## 7.0 FLASH PROGRAM MEMORY

The Flash program memory is readable, writable and erasable during normal operation over the entire VDD range.

A read from program memory is executed on 1 byte at a time. A write to program memory is executed on blocks of 64 bytes at a time or 2 bytes at a time. Program memory is erased in blocks of 512 bytes at a time. A bulk erase operation may not be issued from user code.

Writing or erasing program memory will cease instruction fetches until the operation is complete. The program memory cannot be accessed during the write or erase, therefore, code cannot execute. An internal programming timer terminates program memory writes and erases.

A value written to program memory does not need to be a valid instruction. Executing a program memory location that forms an invalid instruction results in a NOP.

### 7.1 Table Reads and Table Writes

In order to read and write program memory, there are two operations that allow the processor to move bytes between the program memory space and the data RAM:

- Table Read (TBLRD)
- Table Write (TBLWT)

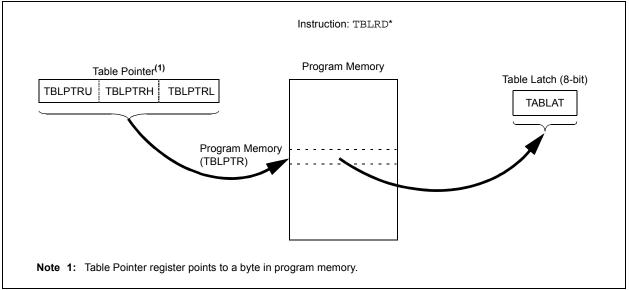

The program memory space is 16 bits wide, while the data RAM space is 8 bits wide. Table reads and table writes move data between these two memory spaces through an 8-bit register (TABLAT).

Table read operations retrieve data from program memory and place it into the data RAM space. Figure 7-1 shows the operation of a table read with program memory and data RAM.

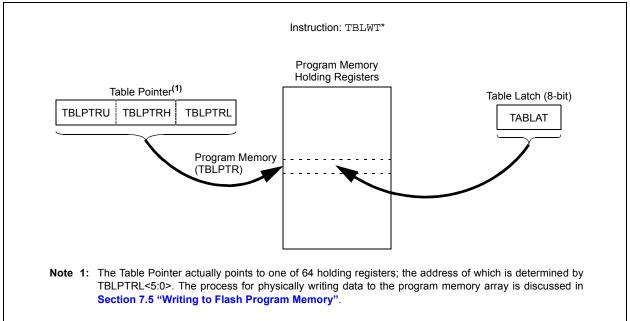

Table write operations store data from the data memory space into holding registers in program memory. The procedure to write the contents of the holding registers into program memory is detailed in **Section 7.5** "Writing **to Flash Program Memory**". Figure 7-2 shows the operation of a table write with program memory and data RAM.

Table operations work with byte entities. A table block containing data, rather than program instructions, is not required to be word-aligned. Therefore, a table block can start and end at any byte address. If a table write is being used to write executable code into program memory, program instructions will need to be word-aligned.

#### FIGURE 7-1: TABLE READ OPERATION

#### 7.2 Control Registers

Several control registers are used in conjunction with the TBLRD and TBLWT instructions. These include:

- EECON1 register
- EECON2 register
- TABLAT register
- TBLPTR registers

#### 7.2.1 EECON1 AND EECON2 REGISTERS

The EECON1 register (Register 7-1) is the control register for memory accesses. The EECON2 register is not a physical register; it is used exclusively in the memory write and erase sequences. Reading EECON2 will read all '0's.

The WWPROG bit, when set, will allow programming two bytes per word on the execution of the WR command. If this bit is cleared, the WR command will result in programming on a block of 64 bytes.

The FREE bit, when set, will allow a program memory erase operation. When FREE is set, the erase operation is initiated on the next WR command. When FREE is clear, only writes are enabled.

The WREN bit, when set, will allow a write operation. On power-up, the WREN bit is clear. The WRERR bit is set in hardware when the WR bit is set, and cleared when the internal programming timer expires and the write operation is complete.

**Note:** During normal operation, the WRERR is read as '1'. This can indicate that a write operation was prematurely terminated by a Reset or a write operation was attempted improperly.

condition.

#### 7.2.2 TABLE LATCH REGISTER (TABLAT)

The Table Latch (TABLAT) is an 8-bit register mapped into the Special Function Register (SFR) space. The Table Latch register is used to hold 8-bit data during data transfers between program memory and data RAM.

#### 7.2.3 TABLE POINTER REGISTER (TBLPTR)

The Table Pointer (TBLPTR) register addresses a byte within the program memory. The TBLPTR is comprised of three SFR registers: Table Pointer Upper Byte, Table Pointer High Byte and Table Pointer Low Byte (TBLPTRU:TBLPTRH:TBLPTRL). These three registers join to form a 22-bit wide pointer. The low-order 21 bits allow the device to address up to 2 Mbytes of program memory space. The 22<sup>nd</sup> bit allows access to the Device ID, the User ID and the Configuration bits.

The Table Pointer register, TBLPTR, is used by the TBLRD and TBLWT instructions. These instructions can update the TBLPTR in one of four ways, based on the table operation. These operations are shown in Table 7-1 and only affect the low-order 21 bits.

#### 7.2.4 TABLE POINTER BOUNDARIES

TBLPTR is used in reads, writes and erases of the Flash program memory.

When a TBLRD is executed, all 22 bits of the TBLPTR determine which byte is read from program memory into TABLAT.

When a TBLWT is executed, the seven Least Significant bits (LSbs) of the Table Pointer register (TBLPTR<6:0>) determine which of the 64 program memory holding registers is written to. When the timed write to program memory begins (via the WR bit), the 12 Most Significant bits (MSbs) of the TBLPTR (TBLPTR<21:10>) determine which program memory block of 1024 bytes is written to. For more detail, see Section 7.5 "Writing to Flash Program Memory".

When an erase of program memory is executed, the 12 MSbs of the Table Pointer register point to the 1024-byte block that will be erased. The LSbs are ignored.

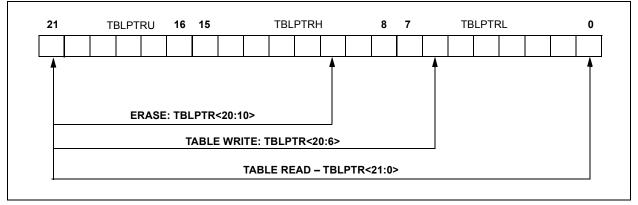

Figure 7-3 describes the relevant boundaries of the TBLPTR based on Flash program memory operations.

#### TABLE 7-1: TABLE POINTER OPERATIONS WITH TBLRD AND TBLWT INSTRUCTIONS

Example	Operation on Table Pointer
TBLRD* TBLWT*	TBLPTR is not modified
TBLRD*+ TBLWT*+	TBLPTR is incremented after the read/write
TBLRD*- TBLWT*-	TBLPTR is decremented after the read/write
TBLRD+* TBLWT+*	TBLPTR is incremented before the read/write

#### FIGURE 7-3:

#### TABLE POINTER BOUNDARIES BASED ON OPERATION

#### 7.3 Reading the Flash Program Memory

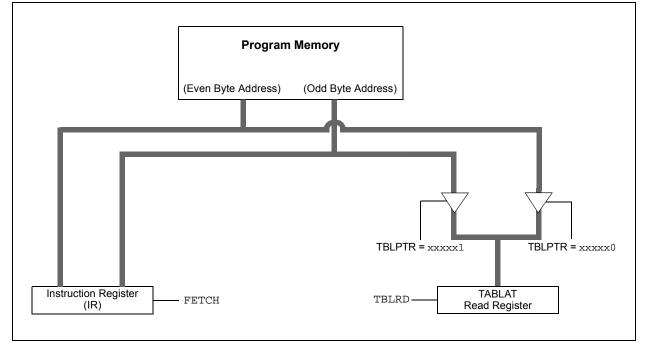

The TBLRD instruction is used to retrieve data from program memory and places it into data RAM. Table reads from program memory are performed one byte at a time.

The TBLPTR points to a byte address in program space. Executing TBLRD places the byte pointed to into TABLAT. In addition, the TBLPTR can be modified automatically for the next table read operation.

The internal program memory is typically organized by words. The Least Significant bit of the address selects between the high and low bytes of the word.

Figure 7-4 shows the interface between the internal program memory and the TABLAT.

#### FIGURE 7-4: READS FROM FLASH PROGRAM MEMORY

	TBLRD*+		;	; read into TABLAT and increment
	MOVF	TABLAT, W	;	; get data
	MOVWF	WORD_ODD		

#### 7.4 Erasing Flash Program Memory

The minimum erase block is 256 words or 512 bytes. Only through the use of an external programmer, or through ICSP control, can larger blocks of program memory be bulk erased. Word erase in the Flash array is not supported.

When initiating an erase sequence from the microcontroller itself, a block of 512 bytes of program memory is erased. The Most Significant 12 bits of the TBLPTR<21:10> point to the block being erased; TBLPTR<9:0> are ignored.

The EECON1 register commands the erase operation. The WREN bit must be set to enable write operations. The FREE bit is set to select an erase operation. For protection, the write initiate sequence for EECON2 must be used.

A long write is necessary for erasing the internal Flash. Instruction execution is halted while in a long write cycle. The long write will be terminated by the internal programming timer.

#### 7.4.1 FLASH PROGRAM MEMORY ERASE SEQUENCE

The sequence of events for erasing a block of internal program memory location is:

- 1. Load Table Pointer register with address of row being erased.
- 2. Set the WREN and FREE bits (EECON1<2,4>) to enable the erase operation.
- 3. Disable interrupts.
- 4. Write 55h to EECON2.
- 5. Write 0AAh to EECON2.
- 6. Set the WR bit; this will begin the erase cycle.
- The CPU will stall for the duration of the erase for TIE (see Parameter D133B).
- 8. Re-enable interrupts.

	BSF	INTCON, GIE	; re-enable interrupts

### 7.5 Writing to Flash Program Memory

The programming block is 32 words or 64 bytes. Programming one word or 2 bytes at a time is also supported.

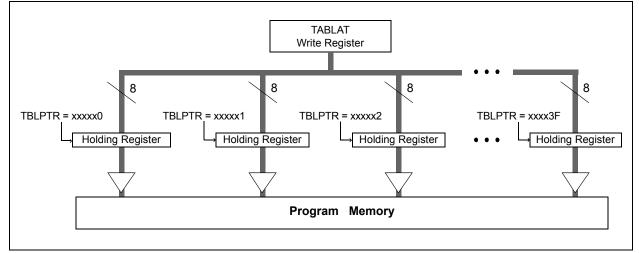

Table writes are used internally to load the holding registers needed to program the Flash memory. There are 64 holding registers used by the table writes for programming.

Since the Table Latch (TABLAT) is only a single byte, the TBLWT instruction may need to be executed 64 times for each programming operation (if WWPROG = 0). All of the table write operations will essentially be short writes because only the holding registers are written. At the end of updating the 64 holding registers, the EECON1 register must be written to in order to start the programming operation with a long write.

The long write is necessary for programming the internal Flash. Instruction execution is halted while in a long write cycle. The long write will be terminated by the internal programming timer. The on-chip timer controls the write time. The write/ erase voltages are generated by an on-chip charge pump, rated to operate over the voltage range of the device.

- **Note 1:** Unlike previous PIC<sup>®</sup> MCUs, devices of the PIC18FXXJ94 do not reset the hold-ing registers after a write occurs. The holding registers must be cleared or overwritten before a programming sequence.
  - 2: To maintain the endurance of the program memory cells, each Flash byte should not be programmed more than once between erase operations. Before attempting to modify the contents of the target cell a second time, an erase of the target page, or a bulk erase of the entire memory, must be performed.

#### FIGURE 7-5: TABLE WRITES TO FLASH PROGRAM MEMORY

#### 7.5.1 FLASH PROGRAM MEMORY WRITE SEQUENCE

The sequence of events for programming an internal program memory location should be:

- 1. Read the 512 bytes into RAM.
- 2. Update the data values in RAM as necessary.
- 3. Load the Table Pointer register with the address being erased.
- 4. Execute the erase procedure.
- 5. Load the Table Pointer register with the address of the first byte being written, minus 1.
- 6. Write the 64 bytes into the holding registers with auto-pre-increment.
- Set the WREN bit (EECON1<2>) to enable byte writes.

- 8. Disable the interrupts.
- 9. Write 55h to EECON2.
- 10. Write 0xAAh to EECON2.
- Set the WR bit. This will begin the write cycle. The CPU will stall for duration of the write for Tiw (see Parameter D133A).
- 12. Re-enable the interrupts.
- 13. Verify the memory (table read).

An example of the required code is shown in Example 7-3 on the following Page 153.

Note: Before setting the WR bit, the Table Pointer address needs to be within the intended address range of the 64 bytes in the holding register.

#### EXAMPLE 7-3: WRITING TO FLASH PROGRAM MEMORY

#### 7.5.2 FLASH PROGRAM MEMORY WRITE SEQUENCE (WORD PROGRAMMING)

The PIC18FXXJ94 of devices has a feature that allows programming a single word (two bytes). This feature is enabled when the WWPROG bit is set. If the memory location is already erased, the following sequence is required to enable this feature:

- 1. Load the Table Pointer register with the address of the data to be written. (It must be an even address.)
- 2. Write the 2 bytes into the holding registers by performing table writes. (Do not post-increment on the second table write).

- Set the WREN bit (EECON1<2>) to enable writes and the WWPROG bit (EECON1<5>) to select Word Write mode.
- 4. Disable interrupts.
- 5. Write 55h to EECON2.
- 6. Write 0AAh to EECON2.
- 7. Set the WR bit; this will begin the write cycle.
- 8. The CPU will stall for the duration of the write for TIW (see Parameter D133A).
- 9. Re-enable interrupts.

#### EXAMPLE 7-4: SINGLE-WORD WRITE TO FLASH PROGRAM MEMORY

	BSF	INTCON, GIE	; re-enable interrupts
	BCF	EECON1, WWPROG	; disable single word write
	BCF	EECON1, WREN	; disable write to memory

#### 7.5.3 WRITE VERIFY

Depending on the application, good programming practice may dictate that the value written to the memory should be verified against the original value. This should be used in applications where excessive writes can stress bits near the specification limit.

## 7.5.4 UNEXPECTED TERMINATION OF WRITE OPERATION

If a write is terminated by an unplanned event, such as loss of power or an unexpected Reset, the memory location just programmed should be verified and reprogrammed if needed. If the write operation is interrupted by a MCLR Reset, or a WDT time-out Reset during normal operation, the user can check the WRERR bit and rewrite the location(s) as needed

#### 7.6 Flash Program Operation During Code Protection

See Section 28.4.5 "Program Verification and Code Protection" for details on code protection of Flash program memory.

### 8.0 EXTERNAL MEMORY BUS

Note:	The	External	Memory	Bus	is	not
	imple	mented on	64-pin dev	ices.		

The External Memory Bus (EMB) allows the device to access external memory devices (such as Flash, EPROM or SRAM) as program or data memory. It supports both 8 and 16-Bit Data Width modes, and three address widths of up to 20 bits.

The bus is implemented with 28 pins, multiplexed across four I/O ports. Three ports (PORTD, PORTE and PORTH) are multiplexed with the address/data bus for a total of 20 available lines, while PORTJ is multiplexed with the bus control signals.

A list of the pins and their functions is provided in Table 8-1.

#### TABLE 8-1: PIC18F97J94 FAMILY EXTERNAL BUS – I/O PORT FUNCTIONS

Name	Port	Bit	External Memory Bus Function

RJ6/LB	PORTJ	6	Lower Byte Enable (LB) Control Pin
RJ7/UB	PORTJ	7	Upper Byte Enable (UB) Control Pin

**Note:** For the sake of clarity, only I/O port and external bus assignments are shown here. One or more additional multiplexed features may be available on some pins.

#### 8.1 External Memory Bus Control

The operation of the interface is controlled by the MEMCON register (Register 8-1). This register is available in all program memory operating modes, except Microcontroller mode. In this mode, the register is disabled and cannot be written to.

The EBDIS bit (MEMCON<7>) controls the operation of the bus and related port functions. Clearing EBDIS enables the interface and disables the I/O functions of the ports, as well as any other functions multiplexed to those pins. Setting the bit enables the I/O ports and other functions, but allows the interface to override everything else on the pins when an external memory operation is required. By default, the external bus is always enabled and disables all other I/O. The operation of the EBDIS bit is also influenced by the program memory mode being used. This is discussed in more detail in Section 8.5 "Program Memory Modes and the External Memory Bus".

The WAITx bits allow for the addition of Wait states to external memory operations. The use of these bits is discussed in **Section 8.3 "Wait States**".

The WMx bits select the particular operating mode used when the bus is operating in 16-Bit Data Width mode. This is discussed in more detail in **Section 8.6 "16-Bit Data Width Modes"**. These bits have no effect when an 8-Bit Data Width mode is selected.

	00 = Byte Write mode: TABLAT data is copied on both MSB and LSB, WRH or WRL will activate

Note 1: This register is unimplemented on 64-pin devices, read as '0'.

#### 8.2 Address and Data Width

The PIC18FXXJ94 of devices can be independently configured for different address and data widths on the same memory bus. Both address and data width are set by Configuration bits in the CONFIG5L register. As Configuration bits, this means that these options can only be configured by programming the device and are not controllable in software.

The BW bit selects an 8-bit or 16-bit data bus width. Setting this bit (default) selects a data width of 16 bits.

The ABW<1:0> bits determine both the program memory operating mode and the address bus width. The available options are 20-bit, 16-bit and 12-bit, as well as Microcontroller mode (external bus disabled). Selecting a 16-bit or 12-bit width makes a corresponding number of high-order lines available for I/O functions. These pins are no longer affected by the setting of the EBDIS bit. For example, selecting a 16-Bit Addressing mode (ABW<1:0> = 01) disables A<19:16> and allows PORTH<3:0> to function without interruptions from the bus. Using the smaller address widths allows users to tailor the memory bus to the size of the external memory space for a particular design while freeing up pins for dedicated I/O operation.

Because the ABWx bits have the effect of disabling pins for memory bus operations, it is important to always select an address width at least equal to the data width. If a 12-bit address width is used with a 16bit data width, the upper four bits of data will not be available on the bus.

All combinations of address and data widths require multiplexing of address and data information on the same lines. The address and data multiplexing, as well as I/O ports made available by the use of smaller address widths, are summarized in Table 8-2.

## 8.2.1 ADDRESS SHIFTING ON THE EXTERNAL BUS

By default, the address presented on the external bus is the value of the PC. In practical terms, this means that addresses in the external memory device, below the top of on-chip memory, are unavailable to the microcontroller. To access these physical locations, the glue logic between the microcontroller and the external memory must somehow translate addresses.

To simplify the interface, the external bus offers an extension of Extended Microcontroller mode that automatically performs address shifting. This feature is controlled by the EASHFT Configuration bit. Setting this bit offsets addresses on the bus by the size of the microcontroller's on-chip program memory and sets the bottom address at 0000h. This allows the device to use the entire range of physical addresses of the external memory.

#### 8.2.2 21-BIT ADDRESSING

As an extension of 20-bit address width operation, the External Memory Bus can also fully address a 2-Mbyte memory space. This is done by using the Bus Address Bit 0 (BA0) control line as the Least Significant bit of the address. The UB and LB control signals may also be used with certain memory devices to select the upper and lower bytes within a 16-bit wide data word.

This addressing mode is available in both 8-Bit and certain 16-Bit Data Width modes. Additional details are provided in Section 8.6.3 "16-Bit Byte Select Mode" and Section 8.7 "8-Bit Data Width Mode".

BLE 6-2: ADDRESS AND DATA LINES FOR DIFFERENT ADDRESS AND DATA WIDTHS								
Data Width	Address Width	Multiplexed Data and Address Lines (and Corresponding Ports)	Address Only Lines (and Corresponding Ports)	Ports Available for I/O				
8-bit	12-bit		AD<11:8> (PORTE<3:0>)	PORTE<7:4>, All of PORTH				
	16-bit	AD<7:0> (PORTD<7:0>)	AD<15:8> (PORTE<7:0>)	All of PORTH				
	20-bit		A<19:16>, AD<15:8> (PORTH<3:0>, PORTE<7:0>)	_				
16-bit	16-bit	AD<15:0>	_	All of PORTH				
	20-bit	(PORTD<7:0>, PORTE<7:0>)	A<19:16> (PORTH<3:0>)	_				

#### TABLE 8-2: ADDRESS AND DATA LINES FOR DIFFERENT ADDRESS AND DATA WIDTHS

#### 8.3 Wait States

While it may be assumed that external memory devices will operate at the microcontroller clock rate, this is often not the case. In fact, many devices require longer times to write or retrieve data than the time allowed by the execution of table read or table write operations.

To compensate for this, the External Memory Bus can be configured to add a fixed delay to each table operation using the bus. Wait states are enabled by setting the WAIT Configuration bit. When enabled, the amount of delay is set by the WAIT<1:0> bits (MEMCON<5:4>). The delay is based on multiples of microcontroller instruction cycle time and is added following the instruction cycle when the table operation is executed. The range is from no delay to 3 Tcy (default value).

#### 8.4 Port Pin Weak Pull-ups

With the exception of the upper address lines, A<19:16>, the pins associated with the External Memory Bus are equipped with weak pull-ups. The pull-ups are controlled by the upper nibble of the PADCFG register (PADCFG<7:4>). They are named RDPU, REPU, RHPU and RJPU, and control pull-ups on PORTD, PORTE, PORTH and PORTJ, respectively. Setting one of these bits enables the corresponding pull-ups for that port. All pull-ups are disabled by default on all device Resets.

In Extended Microcontroller mode, the port pull-ups can be useful in preserving the memory state on the external bus while the bus is temporarily disabled (EBDIS = 1).

#### 8.5 Program Memory Modes and the External Memory Bus

The PIC18FXXJ94 of devices is capable of operating in one of two program memory modes, using combinations of on-chip and external program memory. The functions of the multiplexed port pins depend on the program memory mode selected, as well as the setting of the EBDIS bit.

In **Microcontroller Mode**, the bus is not active and the pins have their port functions only. Writes to the MEMCOM register are not permitted. The Reset value of EBDIS ('0') is ignored and the ABWx pins behave as I/O ports.

In **Extended Microcontroller Mode**, the external program memory bus shares I/O port functions on the pins. When the device is fetching or doing table read/ table write operations on the external program memory space, the pins will have the external bus function.

If the device is fetching and accessing internal program memory locations only, the EBDIS control bit will change the pins from external memory to I/O port functions. When EBDIS = 0, the pins function as the external bus. When EBDIS = 1, the pins function as I/O ports.

If the device fetches or accesses external memory while EBDIS = 1, the pins will switch to the external bus. If the EBDIS bit is set by a program executing from external memory, the action of setting the bit will be delayed until the program branches into the internal memory. At that time, the pins will change from external bus to I/O ports.

If the device is executing out of internal memory when EBDIS = 0, the memory bus address/data and control pins will not be active. They will go to a state where the active address/data pins are tri-state; the  $\overline{CE}$ ,  $\overline{OE}$ , WRH, WRL, UB and LB signals are '1', and ALE and BA0 are '0'. Note that only those pins associated with the current address width are forced to tri-state; the other pins continue to function as I/O. In the case of 16-bit address width, for example, only AD<15:0> (PORTD and PORTE) are affected; A<19:16> (PORTH<3:0>) continue to function as I/O.

In all external memory modes, the bus takes priority over any other peripherals that may share pins with it. This includes the Parallel Master Port and serial communication modules which would otherwise take priority over the I/O port.

#### 8.6 16-Bit Data Width Modes

In 16-Bit Data Width mode, the external memory interface can be connected to external memories in three different configurations:

- 16-Bit Byte Write
- 16-Bit Word Write
- 16-Bit Byte Select

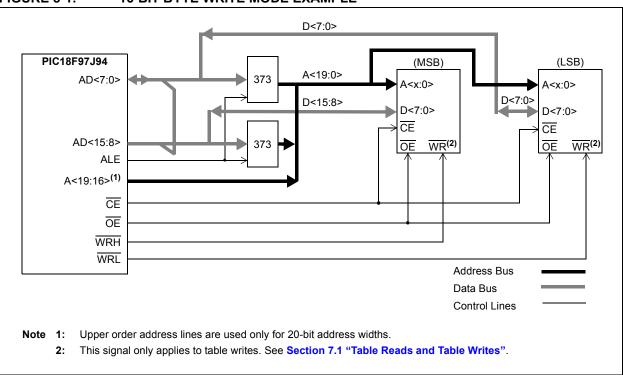

The configuration to be used is determined by the WM<1:0> bits in the MEMCON register (MEMCON<1:0>). These three different configurations allow the designer maximum flexibility in using both 8-bit and 16-bit devices with 16-bit data.

For all 16-bit modes, the Address Latch Enable (ALE) pin indicates that the address bits, AD<15:0>, are available on the external memory interface bus. Following the address latch, the Output Enable ( $\overline{OE}$ ) signal will enable both bytes of program memory at once to form a 16-bit instruction word. The Chip Enable ( $\overline{CE}$  signal) is active at any time that the microcontroller accesses external memory, whether reading or writing; it is inactive (asserted high) whenever the device is in Sleep mode.

In Byte Select mode, JEDEC<sup>®</sup> standard Flash memories will require BA0 for the byte address line and one I/O line to select between Byte and Word mode. The other 16-bit modes do not need BA0. JEDEC standard static RAM memories will use the UB or LB signals for byte selection.

#### 8.6.1 16-BIT BYTE WRITE MODE

Figure 8-1 shows an example of 16-Bit Byte Write mode for PIC18FXXJ94 devices. This mode is used for two separate 8-bit memories connected for 16-bit operation. This generally includes basic EPROM and Flash devices. It allows table writes to byte-wide external memories. During a TBLWT instruction cycle, the TABLAT data is presented on the upper and lower bytes of the AD<15:0> bus. The appropriate WRH or WRL control line is strobed on the LSb of the TBLPTR.

#### FIGURE 8-1: 16-BIT BYTE WRITE MODE EXAMPLE

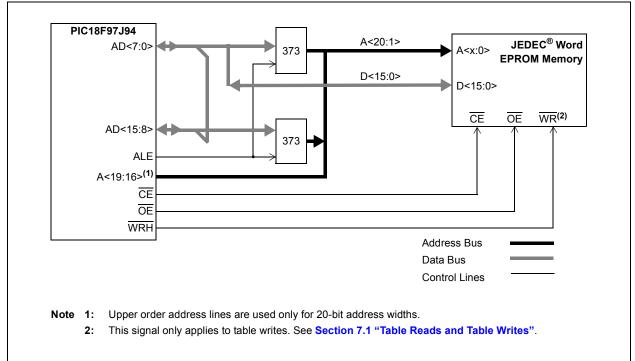

#### 8.6.2 16-BIT WORD WRITE MODE

Figure 8-2 shows an example of 16-Bit Word Write mode for PIC18FXXJ94 devices. This mode is used for word-wide memories, which includes some of the EPROM and Flash-type memories. This mode allows opcode fetches and table reads from all forms of 16-bit memory, and table writes to any type of word-wide external memories. This method makes a distinction between TBLWT cycles to even or odd addresses.

During a TBLWT cycle to an even address (TBLPTR<0> = 0), the TABLAT data is transferred to a holding latch and the external address data bus is tristated for the data portion of the bus cycle. No write signals are activated.

During a TBLWT cycle to an odd address (TBLPTR<0> = 1), the TABLAT data is presented on the upper byte of the AD<15:0> bus. The contents of the holding latch are presented on the lower byte of the AD<15:0> bus.

The WRH signal is strobed for each write cycle; the WRL pin is unused. The signal on the BA0 pin indicates the LSb of the TBLPTR, but it is left unconnected. Instead, the UB and LB signals are active to select both bytes. The obvious limitation to this method is that the table write must be done in pairs on a specific word boundary to correctly write a word location.

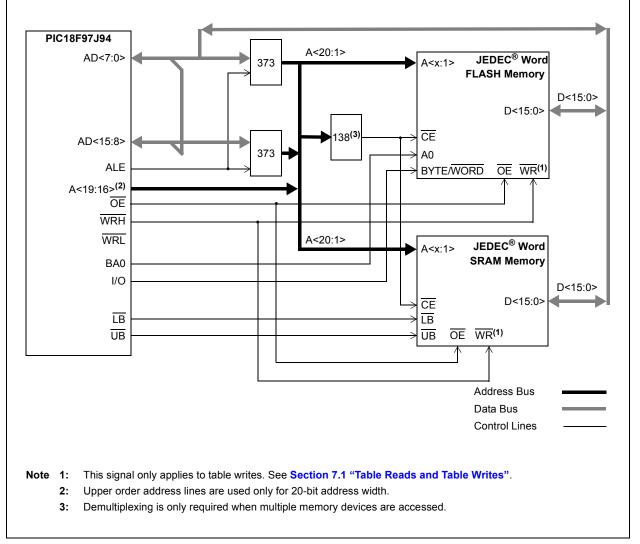

#### FIGURE 8-2: 16-BIT WORD WRITE MODE EXAMPLE

#### 8.6.3 16-BIT BYTE SELECT MODE

Figure 8-3 shows an example of 16-Bit Byte Select mode. This mode allows table write operations to word-wide external memories with byte selection capability. This generally includes both word-wide Flash and SRAM devices.

During a TBLWT cycle, the TABLAT data is presented on the upper and lower byte of the AD<15:0> bus. The WRH signal is strobed for each write cycle; the WRL pin is not used. The BA0 or UB/LB signals are used to select the byte to be written, based on the Least Significant bit of the TBLPTR register. Flash and SRAM devices use different control signal combinations to implement Byte Select mode. JEDEC standard Flash memories require that a controller I/O port pin be connected to the memory's BYTE/WORD pin to provide the select signal. They also use the BA0 signal from the controller as a byte address. JEDEC standard static RAM memories, on the other hand, use the UB or LB signals to select the byte.

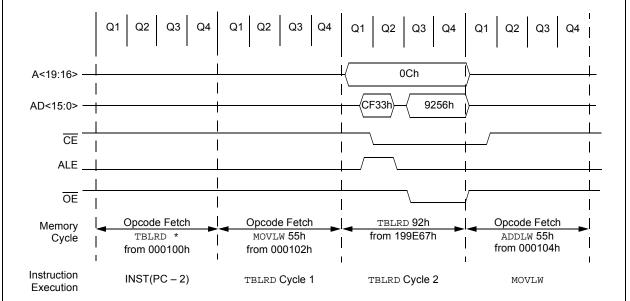

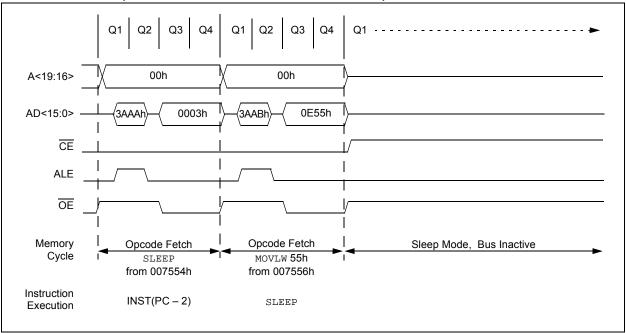

#### 8.6.4 16-BIT MODE TIMING

The presentation of control signals on the External Memory Bus is different for the various operating modes. Typical signal timing diagrams are shown in Figure 8-4 and Figure 8-5.

#### FIGURE 8-5: EXTERNAL MEMORY BUS TIMING FOR SLEEP (EXTENDED MICROCONTROLLER MODE)

#### 8.7 8-Bit Data Width Mode

In 8-Bit Data Width mode, the External Memory Bus operates only in Multiplexed mode; that is, data shares the 8 Least Significant bits of the address bus.

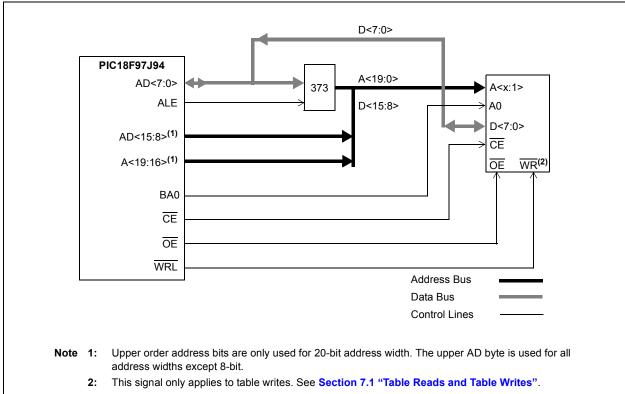

Figure 8-6 shows an example of 8-Bit Multiplexed mode for 100-pin devices. This mode is used for a single, 8-bit memory, connected for 16-bit operation. The instructions will be fetched as two 8-bit bytes on a shared data/address bus. The two bytes are sequentially fetched within one instruction cycle (TcY). Therefore, the designer must choose external memory devices, according to timing calculations based on 1/ 2 TcY (2 times the instruction rate). For proper memory speed selection, glue logic propagation delay times must be considered, along with setup and hold times.

The Address Latch Enable (ALE) pin indicates that the address bits, AD<15:0>, are available on the External Memory Bus interface. The Output Enable (OE) signal

will enable one byte of program memory for a portion of the instruction cycle, then BA0 will change and the second byte will be enabled to form the 16-bit instruction word. The Least Significant bit of the address, BA0, must be connected to the memory devices in this mode. The Chip Enable ( $\overline{CE}$ ) signal is active at any time that the microcontroller accesses external memory, whether reading or writing. It is inactive (asserted high) whenever the device is in Sleep mode.

This generally includes basic EPROM and Flash devices. It allows table writes to byte-wide external memories.

During a TBLWT instruction cycle, the TABLAT data is presented on the upper and lower bytes of the AD<15:0> bus. The appropriate level of the BA0 control line is strobed on the LSb of the TBLPTR.

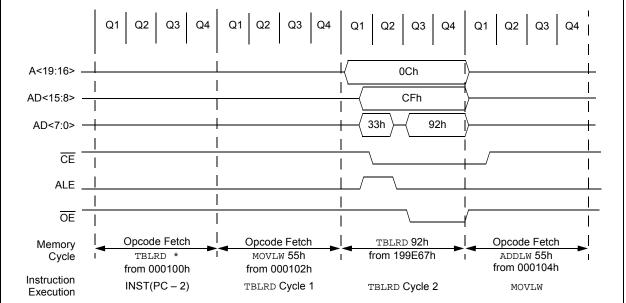

#### FIGURE 8-6: 8-BIT MULTIPLEXED MODE EXAMPLE

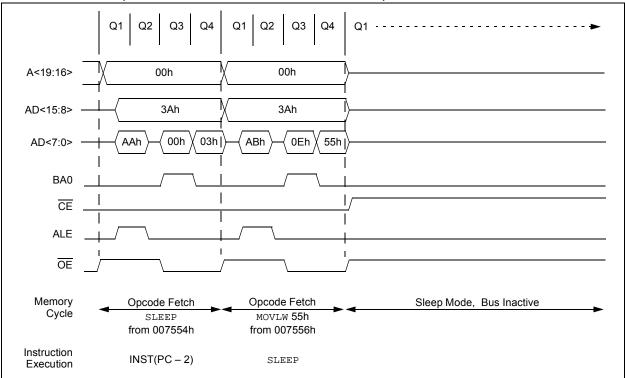

#### 8.7.1 8-BIT MODE TIMING

The presentation of control signals on the External Memory Bus is different for the various operating modes. Typical signal timing diagrams are shown in Figure 8-7 and Figure 8-8.

#### FIGURE 8-8: EXTERNAL MEMORY BUS TIMING FOR SLEEP (EXTENDED MICROCONTROLLER MODE)

#### 8.8 Operation in Power-Managed Modes

In alternate, power-managed Run modes, the external bus continues to operate normally. If a clock source with a lower speed is selected, bus operations will run at that speed. In these cases, excessive access times for the external memory may result if Wait states have been enabled and added to external memory operations. If operations in a lower power Run mode are anticipated, users should provide in their applications for adjusting memory access times at the lower clock speeds. In Sleep and Idle modes, the microcontroller core does not need to access data; bus operations are suspended. The state of the external bus is frozen, with the address/data pins and most of the control pins holding at the same state they were in when the mode was invoked. The only potential changes are to the CE, LB and UB pins, which are held at logic high.

<b>TABLE 8-3</b> :	REGISTERS ASSOCIATED WITH THE EXTERNAL MEMORY BUS

Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0

Note 1: This register is unimplemented on 64-pin devices read as '0'.

## 9.0 8 x 8 HARDWARE MULTIPLIER

#### 9.1 Introduction

All PIC18 devices include an 8 x 8 hardware multiplier as part of the ALU. The multiplier performs an unsigned operation and yields a 16-bit result that is stored in the product register pair, PRODH:PRODL. The multiplier's operation does not affect any flags in the STATUS register.

Making multiplication a hardware operation allows it to be completed in a single instruction cycle. This has the advantages of higher computational throughput and reduced code size for multiplication algorithms and allows PIC18 devices to be used in many applications previously reserved for digital-signal processors. A comparison of various hardware and software multiply operations, along with the savings in memory and execution time, is shown in Table 9-1.

#### 9.2 Operation

Example 9-1 shows the instruction sequence for an 8 x 8 unsigned multiplication. Only one instruction is required when one of the arguments is already loaded in the WREG register.

Example 9-2 shows the sequence to do an 8 x 8 signed multiplication. To account for the sign bits of the arguments, each argument's Most Significant bit (MSb) is tested and the appropriate subtractions are done.

## 10.0 INTERRUPTS

Members of the PIC18F97J94 family of devices have multiple interrupt sources and an interrupt priority feature that allows most interrupt sources to be assigned a high-priority level or a low-priority level. The high-priority interrupt vector is at 0008h and the lowpriority interrupt vector is at 0018h. High-priority interrupt events will interrupt any low-priority interrupts that may be in progress.

The registers for controlling interrupt operation are:

- RCON
- INTCON
- INTCON2
- INTCON3
- PIR1, PIR2, PIR3, PIR4, PIR5 and PIR6
- PIE1, PIE2, PIE3, PIE4, PIE5 and PIE6
- IPR1, IPR2, IPR3, IPR5, IPR5 and IPR6

It is recommended that the Microchip header files, supplied with MPLAB<sup>®</sup> IDE, be used for the symbolic bit names in these registers. This allows the assembler/ compiler to automatically take care of the placement of these bits within the specified register.

In general, interrupt sources have three bits to control their operation. They are:

- Flag bit Indicating that an interrupt event occurred
- Enable bit Enabling program execution to branch to the interrupt vector address when the flag bit is set
- Priority bit Specifying high priority or low priority

#### 10.1 Mid-Range Compatibility

When the IPEN bit is cleared (default state), the interrupt priority feature is disabled and interrupts are compatible with PIC<sup>®</sup> microcontroller mid-range devices. In Compatibility mode, the interrupt priority bits of the IPRx registers have no effect. The PEIE/GIEL bit of the INTCON register is the global interrupt enable for the peripherals. The PEIE/GIEL bit disables only the peripheral interrupt sources and enables the peripheral interrupt sources when the GIE/GIEH bit is also set. The GIE/GIEH bit of the INTCON register is the global interrupt enable which enables all non-peripheral interrupt sources and disables all interrupt sources, including the peripherals. All interrupts branch to address 0008h in Compatibility mode.

### 10.2 Interrupt Priority

The interrupt priority feature is enabled by setting the IPEN bit of the RCON register. When interrupt priority is enabled the GIE/GIEH and PEIE/GIEL global interrupt enable bits of Compatibility mode are replaced by the GIEH high priority, and GIEL low priority, global interrupt enables. When set, the GIEH bit of the INTCON register enables all interrupts that have their associated IPRx register or INTCONx register priority bit set (high priority). When clear, the GIEH bit disables all interrupt sources including those selected as low priority. When clear, the GIEL bit of the INTCON register disables only the interrupts that have their associated priority bit cleared (low priority). When set, the GIEL bit enables the low priority sources when the GIEH bit is also set. When the interrupt flag, enable bit and appropriate Global Interrupt Enable (GIE) bit are all set, the interrupt will vector immediately to address 0008h for high priority, or 0018h for low priority, depending on level of the interrupting source's priority bit. Individual interrupts can be disabled through their corresponding interrupt enable bits.

#### 10.3 Interrupt Response

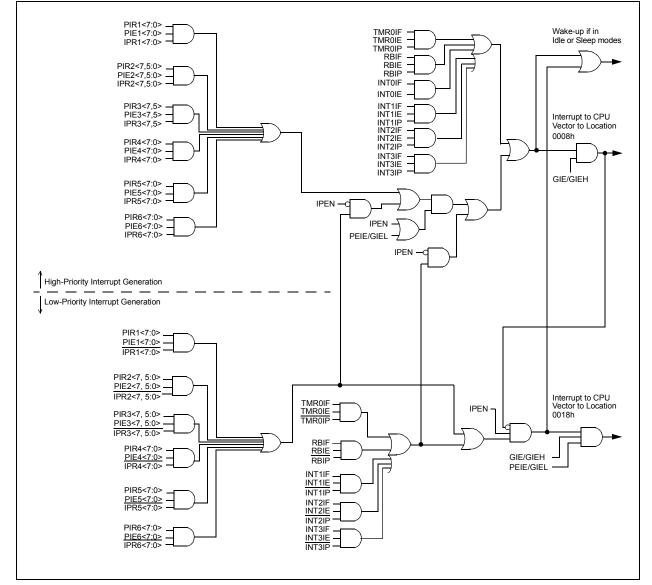

When an interrupt is responded to, the Global Interrupt Enable bit is cleared to disable further interrupts. The GIE/GIEH bit is the global interrupt enable when the IPEN bit is cleared. When the IPEN bit is set, enabling interrupt priority levels, the GIEH bit is the high priority global interrupt enable and the GIEL bit is the low priority global interrupt enable. High priority interrupt sources can interrupt a low priority interrupt. Low priority interrupts are not processed while high priority interrupts are in progress.

The return address is pushed onto the stack and the PC is loaded with the interrupt vector address (0008h or 0018h). Once in the Interrupt Service Routine, the source(s) of the interrupt can be determined by polling the interrupt flag bits in the INTCONx and PIRx registers. The interrupt flag bits must be cleared by software before re-enabling interrupts to avoid repeating the same interrupt.

The "return from interrupt" instruction, RETFIE, exits the interrupt routine and sets the GIE/GIEH bit (GIEH or GIEL if priority levels are used), which re-enables interrupts. For external interrupt events, such as the INT pins or the PORTB interrupt-on-change, the interrupt latency will be three to four instruction cycles. The exact latency is the same for one-cycle or two-cycle instructions. Individual interrupt flag bits are set, regardless of the status of their corresponding enable bits or the Global Interrupt Enable bit.

Note:	Do not use the MOVFF instruction to modify
	any of the Interrupt Control registers while
	any interrupt is enabled. Doing so may
	cause erratic microcontroller behavior.

#### FIGURE 10-1: PIC18F97J94 FAMILY INTERRUPT LOGIC

#### 10.4 INTCON Registers

The INTCON registers are readable and writable registers that contain various enable, priority and flag bits.

Note: Interrupt flag bits are set when an interrupt condition occurs regardless of the state of its corresponding enable bit or the Global Interrupt Enable bit. User software should ensure the appropriate interrupt flag bits are clear prior to enabling an interrupt. This feature allows for software polling.

#### 10.5 PIR Registers

The PIR registers contain the individual flag bits for the peripheral interrupts. Due to the number of peripheral interrupt sources, there are six Peripheral Interrupt Request (Flag) registers (PIR1 through PIR5).

- Note 1: Interrupt flag bits are set when an interrupt condition occurs regardless of the state of its corresponding enable bit or the Global Interrupt Enable bit, GIE (INTCON<7>).
  - 2: User software should ensure the appropriate interrupt flag bits are cleared prior to enabling an interrupt and after servicing that interrupt.

## REGISTER 10-9: PIR6: PERIPHERAL INTERRUPT REQUEST (FLAG) REGISTER 6

#### 10.6 PIE Registers

The PIE registers contain the individual enable bits for the peripheral interrupts. Due to the number of peripheral interrupt sources, there are six Peripheral Interrupt Enable registers (PIE1 through PIE6). When IPEN (RCON<7>) = 0, the PEIE bit must be set to enable any of these peripheral interrupts.

## REGISTER 10-15: PIE6: PERIPHERAL INTERRUPT ENABLE REGISTER 6

## 10.7 IPR Registers

The IPR registers contain the individual priority bits for the peripheral interrupts. Due to the number of peripheral interrupt sources, there are six Peripheral Interrupt Priority registers (IPR1 through IPR6). Using the priority bits requires that the Interrupt Priority Enable (IPEN) bit (RCON<7>) be set.

## 10.9 INTx Pin Interrupts

External interrupts on INT0, INT1, INT2 and INT3 are edge-triggered. INT0 is multiplexed with RB0 pin whereas INT1, INT2 and INT3 can only be used via remappable pins as shown in Table 11-13. If the corresponding INTEDGx bit in the INTCON2 register is set (= 1), the interrupt is triggered by a rising edge. If that bit is clear, the trigger is on the falling edge.

When a valid edge appears on the RBx/INTx pin, the corresponding flag bit, INTxIF, is set. This interrupt can be disabled by clearing the corresponding enable bit, INTxIE. Before re-enabling the interrupt, the flag bit (INTxIF) must be cleared in software in the Interrupt Service Routine.

All external interrupts (INT0, INT1, INT2 and INT3) can wake-up the processor from the power-managed modes if bit, INTxIE, was set prior to going into the power-managed modes. If the Global Interrupt Enable bit (GIE) is set, the processor will branch to the interrupt vector following wake-up.

The interrupt priority for INT1, INT2 and INT3 is determined by the value contained in the Interrupt Priority bits, INT1IP (INTCON3<6>), INT2IP (INTCON3<7>) and INT3IP (INTCON2<1>).

There is no priority bit associated with INTO. It is always a high-priority interrupt source.

## 10.10 TMR0 Interrupt

In 8-bit mode (the default), an overflow in the TMR0 register (FFh  $\rightarrow$  00h) will set flag bit, TMR0IF. In 16-bit mode, an overflow in the TMR0H:TMR0L register pair (FFFFh  $\rightarrow$  0000h) will set TMR0IF.

The interrupt can be enabled/disabled by setting/clearing enable bit, TMR0IE (INTCON<5>). Interrupt priority for Timer0 is determined by the value contained in the interrupt priority bit, TMR0IP (INTCON2<2>). For further details on the Timer0 module, see Section 14.0 "Timer0 Module".

## 10.11 Edge-Selectable Interrupt-on-Change

Interrupt-on-change pins are selected via the PPS register settings and have the option of generating an interrupt on positive or negative transitions, or both. Positive edge events are enabled by setting the corresponding bits in the IOCP register, while negative edge events are enabled by setting the corresponding bits in the IOCN register. For compatibility with the previous interrupt-on-change feature, both the IOCP and IOCN bits should be set. The interrupt can be enabled by setting/clearing the IOCIE (INTCON<3>) bit. Each individual pin can be disabled by clearing both of the corresponding IOCN/IOCP bits. A change event (either positive or negative edge) will cause the corresponding IOCF flag to be set.

Interrupt priority for the edge selectable interrupt-onchange is determined by the interrupt priority bit, IOCIP (INTCON2<0>).

## REGISTER 10-23: IOCP: INTERRUPT-ON-CHANGE POSITIVE EDGE REGISTER

- 1 = An enabled change was detected on the associated pin; this is set when IOCP<x> = 1 and a positive edge was detected on the input pin or when IOCN<x> = 1 and a negative edge was detected on the input pin (clear in software to clear the IOCIF bit)
- 0 = No change was detected or the user cleared the detected change

## 10.12 Context Saving During Interrupts

During interrupts, the return PC address is saved on the stack. Additionally, the WREG, STATUS and BSR registers are saved on the Fast Return Stack.

If a fast return from interrupt is not used (see **Section 6.3 "Data Memory Organization**"), the user may need to save the WREG, STATUS and BSR registers on entry to the Interrupt Service Routine (ISR). Depending on the user's application, other registers also may need to be saved.

Example 10-1 saves and restores the WREG, STATUS and BSR registers during an Interrupt Service Routine.

### EXAMPLE 10-1: SAVING STATUS, WREG AND BSR REGISTERS IN RAM

MOVWF MOVFF MOVFF	W_TEMP STATUS, STATUS_TEMP BSR, BSR_TEMP	; W_TEMP is in virtual bank ; STATUS_TEMP located anywhere ; BSR_TMEP located anywhere

MOVFF	BSR_TEMP, BSR	; Restore BSR
MOVF	W_TEMP, W	; Restore WREG
MOVFF	STATUS_TEMP, STATUS	; Restore STATUS

## 11.0 I/O PORTS

Depending on the device selected and features enabled, there are up to eleven ports available. Some pins of the I/O ports are multiplexed with an alternate function from the peripheral features on the device. In general, when a peripheral is enabled, that pin may not be used as a general purpose I/O pin.

Each port has three memory mapped registers for its operation:

- TRIS register (Data Direction register)
- PORT register (reads the levels on the pins of the device)
- LAT register (Output Latch register)

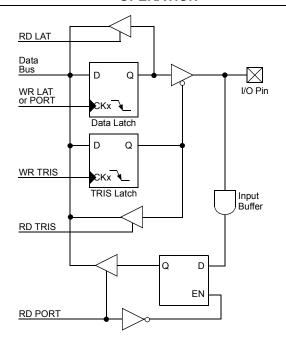

Reading the PORT register reads the current status of the pins, whereas writing to the PORT register, writes to the Output Latch (LAT) register.

Setting a TRIS bit (= 1) makes the corresponding PORT pin an input (putting the corresponding output driver in a High-Impedance mode). Clearing a TRIS bit (= 0) makes the corresponding port pin an output (i.e., driving the contents of the corresponding LAT bit on the selected pin).

The Output Latch (LAT register) is useful for readmodify-write operations on the value that the I/O pins are driving. Read-modify-write operations on the LAT register read and write the latched output value for the PORT register.

A simplified model of a generic I/O port, without the interfaces to other peripherals, is shown in Figure 11-1.

FIGURE 11-1: GENERIC I/O PORT OPERATION

## 11.1 I/O Port Pin Capabilities

When developing an application, the capabilities of the port pins must be considered.

The Absolute Maximum Ratings of the I/O pins are as follows:

- RA2, RA3 = -300mV to (VDD + 300 mV)
- RA6, RA7, RC0, RC1 = -300 mV to (VDD +300 mV)<sup>(1)</sup>
- RF3/RF4 (the USB D+/D- pins) = supports "USB specific levels" (e.g.: -1.0V to +4.6V, but only when the external source impedance is >/= 28 ohms, and the VUSB3V3 pin voltage is >/= 3.0V, otherwise: -500 mV to (VUSB3V3 +500 mV)
- All other general purpose I/O pins (including  $\overline{\text{MCLR}}$ ), when VDD is < 2.0V: -300 mV to +4.0V.
- All other general purpose I/O pins (including MCLR), when VDD is >= 2.0V: -300 mV to +6.0V<sup>(2)</sup>.
  - Note 1: When the pins are used to drive a crystal or ceramic resonator, natural oscillation waveforms slightly exceeding the -300 mV to (VDD +300 mV) range may sometimes occur, and if present, such waveforms are allowed. If these pins are instead used as general purpose inputs, the external driving source should adhere to the -300 mV to (VDD +300 mV) specification.
    - 2: In addition to the above absolute maximums, any I/O pin voltage that is actively selected at runtime by the ADC channel select MUX must also meet the VAIN requirements (parameter A25 in Table 30-40).

## 11.1.1 OUTPUT PIN DRIVE

When used as digital I/O, the output pin drive strengths vary, according to the pins' grouping, to meet the needs for a variety of applications. In general, there are two classes of output pins in terms of drive capability:

- Outputs designed to drive higher current loads, such as LEDs;
  - PORTB
  - PORTC
- Outputs with lower drive levels, but capable of driving normal digital circuit loads with a high input impedance. Able to drive LEDs, but only those with smaller current requirements:
  - PORTA PORTD
  - PORTE PORTF
  - PORTG PORTH<sup>(1)</sup>
  - PORTJ<sup>(1)</sup> PORTK<sup>(2)</sup>
  - PORTL<sup>(2)</sup>
  - Note 1: These ports are not available on 64-pin devices.
    - 2: These ports are not available on 64-pin or 80-pin devices.

## 11.1.2 PULL-UP CONFIGURATION

Nine of the I/O ports (all ports except PORTA and PORTC) implement configurable weak pull-ups on all pins. These are internal pull-ups that allow floating digital input signals to be pulled to a consistent level without the use of external resistors.

Pull-ups for PORTB are enabled by clearing the RBPU bit (INTCON2<7>). PORTB pull-ups are individually selectable through the WPUB register.

Pull-ups for PORTD, PORTE, PORTF, PORTG, PORTH, PORTJ, PORTK and PORTL are enabled through their corresponding enable bits in the PADCFG register, but are not pin-selectable.

## 11.1.3 OPEN-DRAIN OUTPUTS

The output pins for several peripherals are also equipped with a configurable, open-drain output option. This allows the peripherals to communicate with external digital logic, operating at a higher voltage level, without the use of level translators.

The open-drain option is implemented on the EUSARTs, the MSSPx modules (in SPI mode) and the CCP modules. These modules are assigned to an I/O pin using the PPS (Peripheral Pin Select) feature. The open-drain option is enabled by setting the open-drain control bits in the ODCON1 and ODCON2 registers.

When the open-drain option is required, the output pin must also be tied through an external pull-up resistor, provided by the user, to a higher voltage level, up to 5V (Figure 11-2). When a digital logic high signal is output, it is pulled up to the higher voltage level.

#### 11.1.4 ANALOG AND DIGITAL PORTS

Many of the ports multiplex analog and digital functionality, providing a lot of flexibility for hardware designers. PIC18FXXJ94 devices can make any analog pin analog or digital, depending on an application's needs. The ports' analog/digital functionality is controlled by the registers: ANCON1, ANCON2 and ANCON3. Setting these registers makes the corresponding pins analog and clearing the registers makes the ports digital. For details on these registers, see Section 22.0 "12-Bit A/D Converter with Threshold Scan"

## 11.2 PORTA, LATA and TRISA Registers

PORTA is an 8-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISA and LATA.

All PORTA pins have Schmitt Trigger input levels and full CMOS output drivers.

RA<5:0> are multiplexed with analog inputs for the A/D Converter.

The operation of the analog inputs as A/D Converter inputs is selected by clearing or setting the ANSELx control bits in the ANCON1 register. The corresponding TRISA bits control the direction of these pins, even when they are being used as analog inputs. The user must ensure the bits in the TRISA register are maintained set when using them as analog inputs.

**Note:** RA<5:0> are configured as analog inputs on any Reset and are read as '0'.

OSC2/CLKO/RA6 and OSC1/CLKI/RA7 normally serve as the external circuit connections for the External (Primary) Oscillator circuit (HS Oscillator modes), or the external clock input and output (EC Oscillator modes). In these cases, RA6 and RA7 are not available as digital I/O, and their corresponding TRIS and LAT bits are read as '0'. When the device is configured to use either the FRC or LPRC Internal Oscillators as the default oscillator mode, RA6 and RA7 are automatically configured as digital I/O; the oscillator and clock in/ clock out functions are disabled.

## TABLE 11-1: PORTA FUNCTIONS (CONTINUED)

**Legend:** O = Output, I = Input, ANA = Analog Signal, DIG = Digital Output, ST = Schmitt Trigger Buffer Input, x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

## 11.3 PORTB, LATB and TRISB Registers

PORTB is an 8-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISB and LATB. All pins on PORTB are digital only.

#### EXAMPLE 11-2: INITIALIZING PORTB

CLRF	PORTB	; Initialize PORTB by ; clearing output
		; data latches
CLRF	LATB	; Alternate method
		; to clear output
		; data latches
MOVLW	0CFh	; Value used to
		; initialize data
		; direction
MOVWF	TRISB	; Set RB<3:0> as inputs
		; RB<5:4> as outputs
		; RB<7:6> as inputs

Each of the PORTB pins has a weak internal pull-up. A single control bit can turn on all the pull-ups. This is performed by clearing bit, RBPU (INTCON2<7>), and setting the associated WPUB bit. The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on a Power-on Reset.

The RB<3:2> pins are multiplexed as CTMU edge inputs.

## TABLE 11-2:PORTB FUNCTIONS

## TABLE 11-2: PORTB FUNCTIONS (CONTINUED)

Legend: O = Output, I = Input, ANA = Analog Signal, DIG = Digital Output, ST = Schmitt Trigger Buffer Input,

x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

## 11.4 PORTC, LATC and TRISC Registers

PORTC is an 8-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISC and LATC. Only PORTC pins, RC2 through RC7, are digital only pins. The pins have Schmitt Trigger input buffers.

When enabling peripheral functions, use care in defining TRIS bits for each PORTC pin. Some peripherals can override the TRIS bit to make a pin an output or input. Consult the corresponding peripheral section for the correct TRIS bit settings.

**Note:** These pins are configured as digital inputs on any device Reset.

The contents of the TRISC register are affected by peripheral overrides. Reading TRISC always returns the current contents, even though a peripheral device may be overriding one or more of the pins.

TABLE 11-3: PORTC FUNCTIONS (CONTINUED)

**Legend:** O = Output, I = Input, ANA = Analog Signal, DIG = Digital Output, ST = Schmitt Trigger Buffer Input,  $I^2C = I^2C/SMBus$ , x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

## 11.5 PORTD, LATD and TRISD Registers

PORTD is an 8-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISD and LATD.

All pins on PORTD are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

Note:	These pins are configured as digital inputs
	on any device Reset.

Each of the PORTD pins has a weak internal pull-up. A single control bit can turn off all the pull-ups. This is performed by setting bit, RDPU (PADCFG<7>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on all device Resets.

On 80-pin and 100-pin devices, PORTD is multiplexed with the system bus as part of the external memory interface. I/O port and other functions are only available when the interface is disabled by setting the EBDIS bit (MEMCON<7>). When the interface is enabled, PORTD is the low-order byte of the multiplexed Address/Data bus (AD<7:0>). The TRISD bits are also overridden.

PORTD can also be configured as an 8-bit wide microprocessor port (Parallel Slave Port) by setting control bit, PSPMODE (PSPCON<4>). In this mode, the input buffers are TTL. For additional information, see **Section 11.13 "Parallel Slave Port"**.

PORTD also has I<sup>2</sup>C functionality on RD5 and RD6.

EXAMPLE 11-4: INITIALIZING PORTD

## 11.6 PORTE, LATE and TRISE Registers

PORTE is an 8-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISE and LATE.

All pins on PORTE are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

Note:	These pins are configured as digital inputs
	on any device Reset.

Each of the PORTE pins has a weak internal pull-up. A single control bit can turn off all the pull-ups. This is performed by setting bit, REPU (PADCFG<6>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on any device Reset.

For devices operating in Microcontroller mode, the RE7 pin can be configured as the alternate peripheral pin for the ECCP2 module and Enhanced PWM Output 2A.

PORTE is also multiplexed with the Parallel Slave Port address lines. RE2, RE1 and RE0 are multiplexed with the control signals, CS, WR and RD.

RE3 can also be configured as the Reference Clock Output (REFO) from the system clock. For further details, see Section 3.4 "Reference Clock Output Control Module".

x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

## 11.7 PORTF, LATF and TRISF Registers

PORTF is a 6-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISF and LATF. All pins on PORTF are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

Pins, RF2 through RF6, may be used as comparator inputs or outputs by setting the appropriate bits in the CMCON register. To use RF<7:2> as digital inputs, it is also necessary to turn off the comparators.

- **Note 1:** On device Resets, pins, RF<7:2>, are configured as analog inputs and are read as '0'.
  - To configure PORTF as a digital I/O, turn off the comparators and clear ANCON1 and ANCON2 to digital.

#### EXAMPLE 11-6: INITIALIZING PORTF

XCVR = USB Transceiver, x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

## 11.8 PORTG, LATG and TRISG Registers

PORTG width varies depending on pin count. For 64- and 80-pin devices, PORTG is a 6-bit wide, bidirectional port. For 100-pin devices, PORTG is an 8-bit wide bidirectional port. The corresponding Data Direction and Output Latch registers are TRISG and LATG.

PORTG is multiplexed with the EUSART, and CCP, ECCP, Analog, Comparator, RTCC and Timer input functions (Table 11-7). When operating as I/O, all PORTG pins have Schmitt Trigger input buffers. The open-drain functionality for the CCPx and EUSARTx can be configured using ODCONx.

When enabling peripheral functions, care should be taken in defining TRIS bits for each PORTG pin. Some peripherals override the TRIS bit to make a pin an output, while other peripherals override the TRIS bit to make a pin an input. The user should refer to the corresponding peripheral section for the correct TRIS bit settings. The pin override value is not loaded into the TRIS register. This allows read-modify-write of the TRIS register without concern due to peripheral overrides.

#### EXAMPLE 11-7: INITIALIZING PORTG

## 11.9 PORTH, LATH and TRISH Registers

Note:	PORTH is available only on 80-pin and						
	100-pin devices.						

PORTH is an 8-bit wide, bidirectional I/O port. The corresponding Data Direction and Output Latch registers are TRISH and LATH.

All pins on PORTH are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

## TABLE 11-8: PORTH FUNCTIONS (CONTINUED)

Legend: O = Output, I = Input, ANA = Analog Signal, DIG = Digital Output, ST = Schmitt Trigger Buffer Input, x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

## 11.10 PORTJ, LATJ and TRISJ Registers

Note:	PORTJ is available only on 80-pin and
	100-pin devices.

PORTJ is an 8-bit wide, bidirectional port. The corresponding Data Direction and Output Latch registers are TRISJ and LATJ.

All pins on PORTJ are implemented with Schmitt Trigger input buffers. Each pin is individually configurable as an input or output.

Note: These pins are configured as digital inputs on any device Reset.

When the external memory interface is enabled, all of the PORTJ pins function as control outputs for the interface. This occurs automatically when the interface is enabled by clearing the EBDIS control bit (MEMCON<7>). The TRISJ bits are also overridden. Each of the PORTJ pins has a weak internal pull-up. The pull-ups are provided to keep the inputs at a known state for the external memory interface while powering up. A single control bit can turn off all the pull-ups. This is performed by clearing bit, RJPU (PADCFG<2>). The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are disabled on any device Reset.

# TABLE 11-11: PORTL FUNCTIONS

Legend: O = Output, I = Input, ANA = Analog Signal, DIG = Digital Output, ST = Schmitt Trigger Buffer Input,

x = Don't care (TRIS bit does not affect port direction or is overridden for this option).

# 11.13 Parallel Slave Port

PORTD can function as an 8-bit-wide Parallel Slave Port (PSP), or microprocessor port, when control bit, PSPMODE (PSPCON<4>), is set. The port is asynchronously readable and writable by the external world through the RD control input pin (RE0/AD8/LCD-BIAS1/RP28/RD) and WR control input pin (RE1/AD9/ LCDBIAS2/RP29/WR).

Note:	The Parallel Slave Port is available only in
	Microcontroller mode.

The PSP can directly interface to an 8-bit microprocessor data bus. The external microprocessor can read or write the PORTD latch as an 8-bit latch.

Setting bit, PSPMODE, enables port pin, RE0/AD8/ LCDBIAS1/RP28/RD, to be the RD input, RE1/AD9/ LCDBIAS2/RP29/WR to be the WR input and RE2/ AD10/LCDBIAS3/RP30/CS to be the CS (Chip Select) input. For this functionality, the corresponding data direction bits of the TRISE register (TRISE<2:0>) must be configured as inputs ('111').

A write to the PSP occurs when both the  $\overline{\text{CS}}$  and  $\overline{\text{WR}}$  lines are first detected low and ends when either are detected high. The PSPIF and IBF flag bits (PIR1<7> and PSPCON<7>, respectively) are set when the write ends.

A read from the PSP occurs when both the  $\overline{\text{CS}}$  and  $\overline{\text{RD}}$  lines are first detected low. The data in PORTD is read out and the OBF bit (PSPCON<6>) is set. If the user writes new data to PORTD to set OBF, the data is immediately read out, but the OBF bit is not set.

When either the  $\overline{CS}$  or  $\overline{RD}$  line is detected high, the PORTD pins return to the input state and the PSPIF bit is set. User applications should wait for PSPIF to be set before servicing the PSP. When this happens, the IBF and OBF bits can be polled and the appropriate action taken.

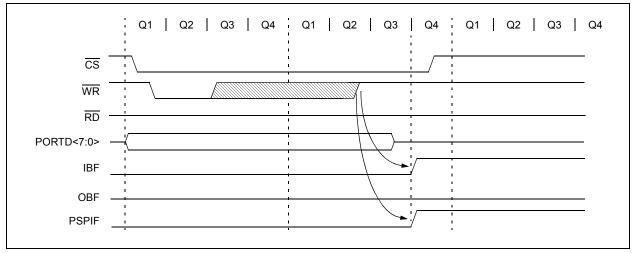

The timing for the control signals in Write and Read modes is shown in Figure 11-4 and Figure 11-5, respectively.

#### 11.14 Virtual PORT

This device includes a single virtual port, which is used to construct a logically addressed 8-bit PORT from 8 physically unrelated pins on the device. The virtual PORT is controlled through the PORTVP, LATVP and TRISVP registers. These function identically to the PORT, LAT and TRIS registers of the actual I/O ports. Refer to **Section 11.1 "I/O Port Pin Capabilities**" for more information.

# 11.15 PPS-Lite

Previous PIC18 devices had I/O pins that were "hardwired" to a set of peripherals. For example, a port pin might have had the option of serving as an I/O pin, an analog input or as an interrupt source. In an effort to increase the flexibility of the parts, PIC18FXXJ94 devices contain PPS-Lite (Peripheral Pin Select-Lite), which allows the developer to connect an internal peripheral to a subset of pins. PPS-Lite is similar to PPS (available on PIC18F products), but limits the user to interconnections within four sets of pin/peripheral groups.

The PPS-Lite feature allows some flexibility in choosing which peripheral connects to any particular pin. This allows designs to be maximized for layout efficiency, and also may allow component changes without changing the printed circuit board design. The Peripheral Pin Select feature operates over a fixed subset of digital I/O pins (those designated as RPn pins). Users may independently map the input and/or output of most digital peripherals to a limited set of these I/O pins. The PPS-Lite configuration is performed in software and does not require the device to be reprogrammed. Hardware safeguards are included that prevent accidental or spurious changes to the peripheral mapping once it has been established.

#### 11.15.1 AVAILABLE PINS

The PPS-Lite feature is used with a range of pins. All devices in the PIC18FXXJ94 family contain a total of 47 remappable peripheral pins, labeled RP0 through RP46. Pins that support PPS-Lite feature include the designation, "RPn" in their full pin designation, where "RP" designates a remappable peripheral and "n" is the remappable pin number. For PIC18FXXJ94 devices, RP41 through RP45 are digital inputs only.

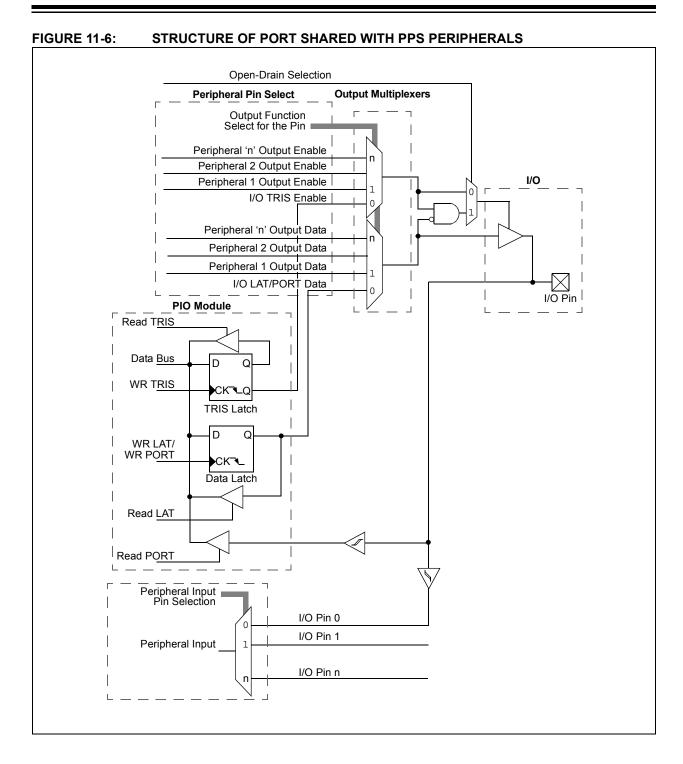

#### 11.15.2 AVAILABLE PERIPHERALS

The peripherals managed by the Peripheral Pin Select are all "digital only" peripherals. These include general serial communications (USART and SPI), general purpose timer clock inputs, timer related peripherals (input capture and output compare) and external interrupt inputs.

In comparison, some digital only peripheral modules are not currently included in the Peripheral Pin Select feature. This is because the peripheral's function requires special I/O circuitry on a specific port and cannot be easily connected to multiple pins. These modules include I<sup>2</sup>C, USB, change notification inputs, RTCC alarm output and all modules with analog inputs, such as the A/D Converter.

A key difference between remappable and non-remappable peripherals is that remappable peripherals are not associated with a default I/O pin. The peripheral must always be assigned to a specific I/O pin before it can be used. In contrast, non-remappable peripherals are always available on a default pin, assuming that the peripheral is active and not conflicting with another peripheral.

When a remappable peripheral is active on a given I/O pin, it takes priority over all other digital I/O and digital communication peripherals associated with the pin. Priority is given, regardless of the type of peripheral that is mapped. Remappable peripherals never take priority over any analog functions associated with the pin.

#### 11.15.3 CONTROLLING PERIPHERAL PIN SELECT

Peripheral Pin Select features are controlled through two sets of Special Function Registers (SFRs): one to map peripheral inputs and one to map peripheral outputs. Because they are separately controlled, a particular peripheral's input and output (if the peripheral has both) can be placed on any selectable function with the only constraint being that RPn peripherals and pins can only be mapped within their own group. It is not possible to map a peripheral to a pin outside of its group or vice versa.

The association of a peripheral to a peripheral-selectable pin is handled in two different ways, depending if an input or output is being mapped.

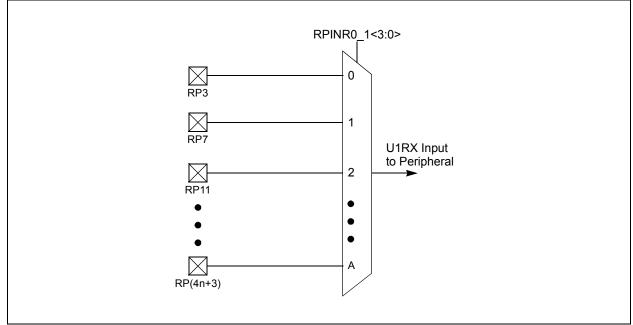

#### 11.15.3.1 Input Mapping

The inputs of the Peripheral Pin Select options are mapped on the basis of the peripheral; that is, a bit field associated with a peripheral dictates the pin it will be mapped to. The RPINRx registers (refer to registers in Table 11-12 and Table 11-13) contain sets of 4-bit fields, with each set associated with one of the remappable peripherals. Programming a given peripheral's bit field with an RPn value maps the RPn pin to that peripheral. For any given device, the valid range of values for any of the bit fields corresponds to the maximum number of peripheral Pin Selections supported by the device.

The PPS-Lite peripheral inputs and associated RPn pins have been organized into four groups. It is not possible to map a peripheral to an RPn pin which is outside of its group. To map a peripheral input signal to an RPn pin, use the 4-step process as indicated in Table 11-13. Choose the signal and the RPn pin, and the column on the right shows which value to write to the associated RPIN register.

The peripheral inputs that support Peripheral Pin Selection have no default pins. Since the implemented bit fields of RPINRx registers reset to all '1's, the inputs are all tied to Vss in the device's default (Reset) state.

For example, to assign U1RX to RP3, write the value, h'0, to RPINR0\_1<3:0>. Figure 11-7 illustrates remappable pin selection for the U1RX input.

# TABLE 11-13: RPIN REGISTERS AND AVAILABLE FUNCTIONS (CONTINUED)

### 11.15.3.2 Output Mapping

In contrast to the inputs, the outputs of the Peripheral Pin Select options are mapped on the basis of the pin. In this case, a bit field associated with a particular pin dictates the peripheral output to be mapped. The RPORx registers contain sets of 4-bit fields, with each associated with one RPn pin (see Register 11-5). The value of the bit field corresponds to one of the peripherals and that peripheral's output is mapped to the pin. Each pin has a limited set of peripherals to choose from.

The PPS-Lite peripheral outputs and associated RPn pins have been organized into four groups. It is not possible to map a peripheral to an RPn pin which is outside of its group. To map a peripheral output signal to

an RPn pin, use the 4-step process, as indicated in Table 11-14. Choose the RPn pin and the signal; the column on the right shows which value to write to the associated RPORx register.

The peripheral outputs that support Peripheral Pin Selection have no default pins. Since the RPORx registers reset to all '0's, the outputs are all disconnected in the device's default (Reset) state.

The list of peripherals for output mapping also includes a null value of b'0000' because of the mapping technique. This allows unused peripherals to not be connected to a pin. Not all peripherals are available on all pins. For example, the "SDO2" signal is only available on RP0, RP4, RP8, etc. The "SDO2" signal is not available on RP1.

# 11.15.3.3 I/O Mapping

While most peripheral signals are defined as either input or output, some peripheral signals switch between input and output: UnRX\_DT, UnTX\_CK, PBIO and CCP. Most commonly, these signals are mapped so that both the input and output map to the same RPn pin. If desired, the input and output can be mapped to separate pins. For standard peripheral operation, ensure that both the input and output mapping configurations select the same RPn pin.

#### 11.15.3.4 Mapping Limitations

The control schema of Peripheral Select Pins is not limited to a small range of fixed peripheral configurations. There are no mutual or hardware enforced lockouts between any of the peripheral mapping SFRs. While such mappings may be technically possible from a configuration point of view, the user must ensure the selected configurations are supportable from an electrical point of view.

h'E h'F

# 11.15.4 CONTROLLING CONFIGURATION CHANGES

Because peripheral remapping can be changed during run time, some restrictions on peripheral remapping are needed to prevent accidental configuration changes. PIC18FXXJ94 devices include two features to prevent alterations to the peripheral map:

Continuous state monitoring

RVP7

Reserved

· Configuration bit remapping lock

#### 11.15.4.1 Control Register Lock

The contents of RPINRx and RPORx registers are constantly monitored in hardware by shadow registers. If an unexpected change in any of the registers occurs (such as cell disturbances caused by ESD or other external events), a Configuration Mismatch Reset will trigger.

#### 11.15.4.2 Configuration Bit Pin Select Lock

As an additional level of safety, the device can be configured to prevent more than one write session to the RPINRx and RPORx registers. The IOL1WAY Configuration bit (CONFIG5H<0>) blocks the IOLOCK bit from being cleared after it has been set once.

In the default (unprogrammed) state, IOL1WAY is set, restricting users to one write session. Programming IOL1WAY allows users unlimited access to the Peripheral Pin Select registers. It is good programming practice to always set the IOLOCK bit (OSCCON2<6>) after all changes have been made to PPS-Lite registers.

#### 11.15.5 CONSIDERATIONS FOR PERIPHERAL PIN SELECTION

The ability to control Peripheral Pin Selection introduces several considerations into application design that should be considered. This is particularly true for several common peripherals which are only available as remappable peripherals.

Before any other application code is executed, the user must initialize the device with the proper peripheral configuration. Since the IOLOCK is not active in the Reset state, the peripherals can be configured, and the IOLOCK bit can be set when configuration is complete.

Choosing the configuration requires the review of all Peripheral Pin Selects and their pin assignments, especially those that will not be used in the application. In all cases, unused pin-selected peripherals should be disabled. Unused peripherals should have their inputs assigned to Vss. I/O pins with unused RPn functions should be configured with the NULL ('0') peripheral output. The assignment of an RPn pin to the peripheral input or output depends on the peripheral and its use in the application. It is good programming practice to map peripherals to pins immediately after Reset. This should be done before any configuration changes to the peripheral itself.

The assignment of a peripheral output to a particular pin does not automatically perform any other configuration of the pin's I/O circuitry. This means adding a pinselectable output to a pin may mean inadvertently driving an existing peripheral input when the output is driven. Users must be familiar with the behavior of other fixed peripherals that share a remappable pin. To be safe, fixed digital peripherals that share the same pin should be disabled when not in use.

Configuring a remappable pin for a specific peripheral input does not automatically turn that feature on. The peripheral must be specifically configured for operation and enabled, as if it were tied to a fixed pin.

A final consideration is that Peripheral Pin Select functions neither override analog inputs, nor reconfigure pins with analog functions for digital I/O. If a pin is configured as an analog input on device Reset, it must be explicitly reconfigured as digital I/O when used with a Peripheral Pin Select.

#### 11.15.5.1 Basic Steps to Use Peripheral Pin Selection Lite (PPS-Lite)

- 1. Disable any fixed digital peripherals on the pins to be used.
- Switch pins to be used for digital functionality (if they have analog functionality) using the ANCONx registers.
- 3. Clear the IOLOCK bit (OSCCON<6>) if needed (not needed after a device Reset).
- 4. Set RPINRx and RPORx registers appropriately.
- 5. Set the IOLOCK bit (OSCCON<6>).
- 6. Enable and configure newly mapped PPS-Lite peripherals.

# 12.0 DATA SIGNAL MODULATOR

The Data Signal Modulator (DSM) is a peripheral which allows the user to mix a data stream, also known as a modulator signal, with a carrier signal to produce a modulated output.

Both the carrier and the modulator signals are supplied to the DSM module, either internally from the output of a peripheral, or externally through an input pin.

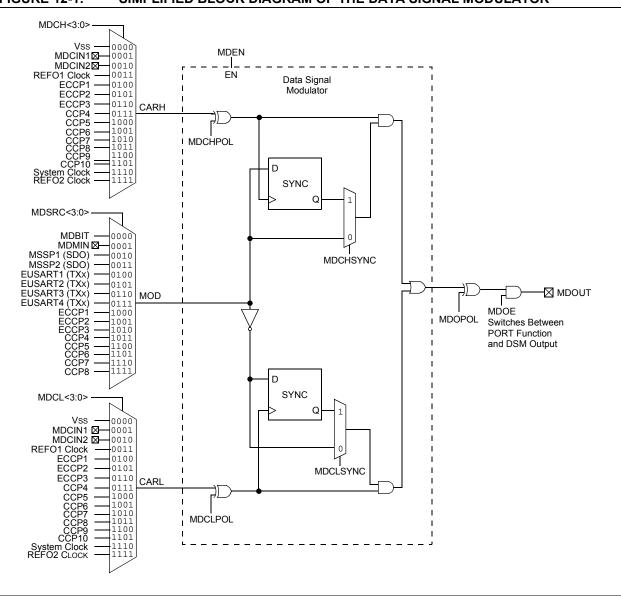

The carrier signal is comprised of two distinct and separate signals: a Carrier High (CARH) signal and a Carrier Low (CARL) signal. During the time in which the Modulator (MOD) signal is in a logic high state, the DSM mixes the Carrier High signal with the Modulator signal. When the Modulator signal is in a logic low state, the DSM mixes the Carrier Low signal with the Modulator signal. Using this method, the DSM can generate the following types of key modulation schemes:

- Frequency-Shift Keying (FSK)
- Phase-Shift Keying (PSK)
- On-Off Keying (OOK)

Additionally, the following features are provided within the DSM module:

- Carrier Synchronization
- · Carrier Source Polarity Select
- Carrier Source Pin Disable
- Programmable Modulator Data
- Modulator Source Pin Disable
- Modulator Output Polarity Select
- Slew Rate Control

Figure 12-1 shows a simplified block diagram of the Data Signal Modulator peripheral.

#### FIGURE 12-1: SIMPLIFIED BLOCK DIAGRAM OF THE DATA SIGNAL MODULATOR

# 12.1 DSM Operation

The DSM module can be enabled by setting the MDEN bit in the MDCON register. Clearing the MDEN bit in the MDCON register disables the DSM module by automatically switching the Carrier High and Carrier Low signals to the VSS signal source. The Modulator signal source is also switched to the MDBIT in the MDCON register. This not only assures that the DSM module is inactive, but that it is also consuming the least amount of current.

The Modulation Carrier High and Modulation Carrier Low Control registers are not affected when the MDEN bit is cleared, and the DSM module is disabled. The values inside these registers remain unchanged while the DSM is inactive. The sources for the Carrier High, Carrier Low and Modulator signals will once again be selected when the MDEN bit is set, and the DSM module is again enabled and active.

The modulated output signal can be disabled without shutting down the DSM module. The DSM module will remain active and continue to mix signals, but the output value will not be sent to the MDOUT pin. During the time that the output is disabled, the MDOUT pin will remain low. The modulated output can be disabled by clearing the MDOE bit in the MDCON register.

# 12.2 Modulator Signal Sources

The Modulator signal can be supplied from the following sources:

- ECCP1 Signal
- ECCP2 Signal
- ECCP3 Signal
- CCP2 Signal
- CCP3 Signal
- CCP4 Signal
- CCP5 Signal
- CCP6 Signal
- CCP7 Signal
- CCP8 Signal
- MSSP1 SDO Signal (SPI mode only)
- MSSP2 SDO Signal (SPI mode only)
- EUSART1 TX1 Signal
- EUSART2 TX2 Signal
- EUSART3 TX3 Signal
- EUSART4 TX4 Signal
- External Signal on MDMIN Pin (RF0/MDMIN)
- MDBIT bit in the MDCON Register

The Modulator signal is selected by configuring the MDSRC<3:0> bits in the MDSRC register.

# 12.3 Carrier Signal Sources

The Carrier High signal and Carrier Low signal can be supplied from the following sources:

- ECCP1 Signal
- ECCP2 Signal
- ECCP3 Signal
- CCP5 Signal
- CCP6 Signal
- CCP7 Signal
- CCP8 Signal
- CCP9 Signal
- CCP10 Signal
- Reference Clock Output Module Signal (REFO1)
- Reference Clock Output Module Signal (REFO2)
- System Clock
- External Signals on the MDCIN1 and MDCIN2 pins are available though PPS. Refer to Section 11.15 "PPS-Lite" for setup.
- Vss

The Carrier High signal is selected by configuring the MDCH<3:0> bits in the MDCARH register. The Carrier Low signal is selected by configuring the MDCL<3:0> bits in the MDCARL register.

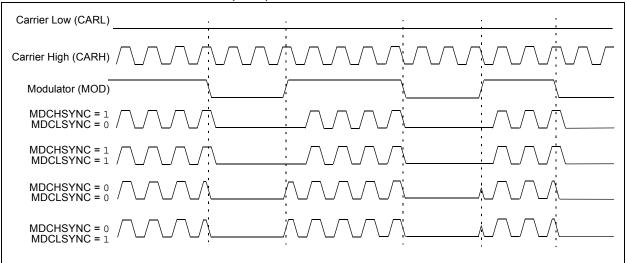

# 12.4 Carrier Synchronization

During the time when the DSM switches between Carrier High and Carrier Low signal sources, the carrier data in the modulated output signal can become truncated. To prevent this, the carrier signal can be synchronized to the Modulator signal. When synchronization is enabled, the carrier pulse that is being mixed at the time of the transition is allowed to transition low before the DSM switches over to the next carrier source.

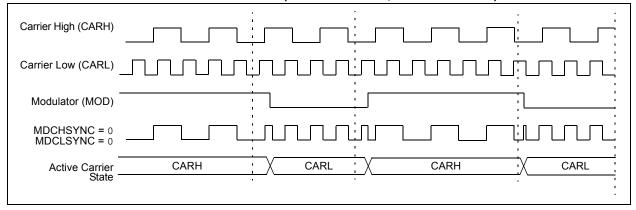

Synchronization is enabled separately for the Carrier High and Carrier Low signal sources. Synchronization for the Carrier High signal can be enabled by setting the MDCHSYNC bit in the MDCARH register. Synchronization for the Carrier Low signal can be enabled by setting the MDCLSYNC bit in the MDCARL register.

Figure 12-1 through Figure 12-6 show timing diagrams using various synchronization methods.

#### FIGURE 12-2: ON-OFF KEYING (OOK) SYNCHRONIZATION

### FIGURE 12-6: FULL SYNCHRONIZATION (MDCHSYNC = 1, MDCLSYNC = 1)

# 12.5 Carrier Source Polarity Select

The signal provided from any selected input source for the Carrier High and Carrier Low signals can be inverted. Inverting the signal for the Carrier High source is enabled by setting the MDCHPOL bit of the MDCARH register. Inverting the signal for the Carrier Low source is enabled by setting the MDCLPOL bit of the MDCARL register.

# 12.6 Carrier Source Pin Disable

Some peripherals assert control over their corresponding output pin when they are enabled. For example, when the CCP1 module is enabled, the output of CCP1 is connected to the CCP1 pin.

This default connection to a pin can be disabled by setting the MDCHODIS bit in the MDCARH register for the Carrier High source and the MDCLODIS bit in the MDCARL register for the Carrier Low source.

# 12.7 Programmable Modulator Data

The MDBIT of the MDCON register can be selected as the source for the Modulator signal. This gives the user the ability to program the value used for modulation.

# 12.8 Modulator Source Pin Disable

The Modulator source default connection to a pin can be disabled by setting the MDSODIS bit in the MDSRC register.

# 12.9 Modulated Output Polarity

The modulated output signal provided on the MDOUT pin can also be inverted. Inverting the modulated output signal is enabled by setting the MDOPOL bit of the MDCON register.

# 12.10 Slew Rate Control

When modulated data streams of 20 MHz or greater are required, the slew rate limitation on the output port pin can be disabled. The slew rate limitation can be removed by clearing the MDSLR bit in the MDCON register.

# 12.11 Operation In Sleep Mode

The DSM module is not affected by Sleep mode. The DSM can still operate during Sleep if the carrier and Modulator input sources are also still operable during Sleep.

# 12.12 Effects of a Reset

Upon any device Reset, the Modulator data signal module is disabled. The user's firmware is responsible for initializing the module before enabling the output. The registers are reset to their default values.

# 13.0 LIQUID CRYSTAL DISPLAY (LCD) CONTROLLER

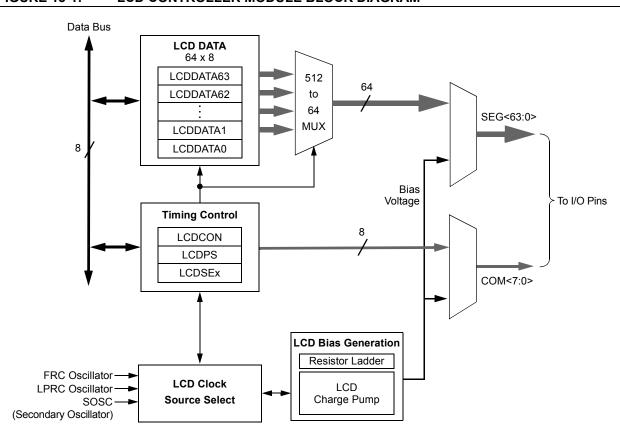

The Liquid Crystal Display (LCD) driver module generates the timing control to drive a static or multiplexed LCD panel. In 100-pin devices (PIC18F97J94), the module drives panels of up to eight commons and up to 60 segments when 5 to 8 commons are used, and up to 64 segments when 1 to 4 commons are used. It also provides control of the LCD pixel data.

The LCD driver module supports:

- · Direct driving of LCD panel
- · Three LCD clock sources with selectable prescaler
- · Up to eight commons:
  - Static (One common)
  - 1/2 multiplex (two commons)
  - 1/3 multiplex (three commons)
  - 1/8 multiplex (eight commons)

- Up to 60 segments (in 100-pin devices when 1/5-1/8 multiplex is selected), 64 (in 100-pin devices when up to 1/4 multiplex is selected), 46 (in 80-pin devices when 1/5-1/8 multiplex is selected), 50 (in 80-pin devices when up to 1/4 multiplex is selected), 30 (in 64-pin devices when 1/5-1/8 multiplex is selected) and 34 (in 64-pin devices when up to 1/4 multiplex is selected)
- Static, 1/2 or 1/3 LCD bias
- On-chip bias generator with dedicated charge pump to support a range of fixed and variable bias options
- · Internal resistors for bias voltage generation
- Software contrast control for LCD using the internal biasing

A simplified block diagram of the module is shown in Figure 13-1.

#### FIGURE 13-1: LCD CONTROLLER MODULE BLOCK DIAGRAM

# 13.1 LCD Registers

The LCD controller has up to 77 registers:

- LCD Control Register (LCDCON)
- LCD Phase Register (LCDPS)
- LCD Voltage Regulator Control Register (LCDREG)
- LCD Reference Ladder Control Register (LCDREF and LCDRL)
- Eight LCD Segment Enable Registers (LCDSE7:LCDSE0)
- 64 LCD Data Registers (LCDDATA63:LCDDA-TA0)

The LCDCON register, shown in Register 13-1, controls the overall operation of the module. Once the module is configured, the LCDEN (LCDCON<7>) bit is used to enable or disable the LCD module. The LCD panel can also operate during Sleep by clearing the SLPEN (LCDCON<6>) bit.

The LCDPS register, shown in Register 13-3, configures the LCD clock source prescaler and the type of waveform: Type-A or Type-B. For details on these features, see Section 13.3 "LCD Clock Source Selection" and Section 13.12 "LCD Waveform Generation".

# 13.2 LCD Segment Pins Configuration

The LCDSEx registers configure the functions of the port pins. Setting the segment enable bit for a particular segment configures that pin as an LCD driver. There

are four LCD Segment Enable registers, as shown in Table 13-1. The prototype LCDSEx register is shown in Register 13-4.

### TABLE 13-1: LCDSEx REGISTERS AND ASSOCIATED SEGMENTS

LCDSE7	Seg 63:Seg 56

Once the module is initialized for the LCD panel, the individual bits of the LCDDATAx registers are cleared or set to represent a clear or dark pixel, respectively.

Specific sets of LCDDATA registers are used with specific segments and common signals. Each bit represents a unique combination of a specific segment connected to a specific common.

Individual LCDDATA bits are named by the convention, "SxxCy", with "xx" as the segment number and "y" as the common number. The relationship is summarized in Register 13-3. The prototype LCDDATAx register is shown in Register 13-5.

# 13.3 LCD Clock Source Selection

The LCD driver module has three possible clock sources:

- FRC/8192
- SOSC Clock/32
- LPRC/32

The first clock source is the 8 MHz Fast Internal RC (FRC) Oscillator divided by 8,192. This divider ratio is chosen to provide about 1 kHz output. The divider is not programmable. Instead, the LCD prescaler bits, LCDPS<3:0>, are used to set the LCD frame clock rate.

The second clock source is the SOSC Oscillator/32. This also outputs about 1 kHz when a 32.768 kHz crystal is used with the SOSC Oscillator. To use the SOSC Oscillator as a clock source, set the SOSCEN (T1CON<3>) bit.

The third clock source is a 31.25 kHz internal LPRC Oscillator/32 that provides approximately 1 kHz output.

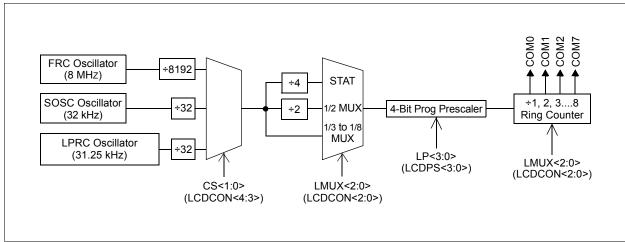

The second and third clock sources may be used to continue running the LCD while the processor is in Sleep.

These clock sources are selected through the bits, CS<1:0> (LCDCON<4:3>).

#### 13.3.1 LCD PRESCALER

A 16-bit counter is available as a prescaler for the LCD clock. The prescaler is not directly readable or writable. Its value is set by the LP<3:0> bits (LCDPS<3:0>) that determine the prescaler assignment and prescale ratio.

Selectable prescale values are from 1:1 through 1:16, in increments of one.

#### FIGURE 13-2: LCD CLOCK GENERATION

# 13.4 LCD Bias Types

The LCD module can be configured in one of three bias types:

- Static bias (two voltage levels: Vss and VDD)
- 1/2 bias (three voltage levels: Vss, 1/2 VDD and VDD)
- 1/3 bias (four voltage levels: Vss, 1/3 VDD, 2/3 VDD and VDD)

LCD bias voltages can be generated with internal resistor ladders, internal bias generator or external resistor ladder.

## 13.5 Internal Resistor Biasing

This mode does not use external resistors, but rather internal resistor ladders that are configured to generate the bias voltage.

The internal reference ladder actually consists of three separate ladders. Disabling the internal reference ladder disconnects all of the ladders, allowing external voltages to be supplied.

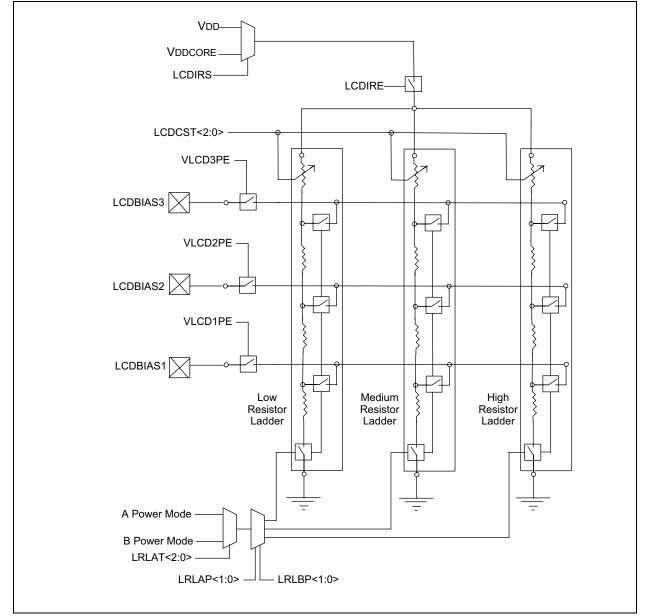

Depending on the total resistance of the resistor ladders, the biasing can be classified as low, medium or high power.

Table 13-3 shows the total resistance of each of the ladders. Table 13-3 shows the internal resister ladder connections. When the internal resistor ladder is selected, the bias voltage can either be from VDD or from VDDCORE, depending on the LCDIRS setting. It can also provide software contrast control (using LCDCST<2:0>)

Power Mode	Nominal Resistance of Entire Ladder	IDD
Low	3 ΜΩ	1 µA
Medium	300 kΩ	10 µA
High	30 kΩ	100 µA

#### TABLE 13-3: INTERNAL RESISTANCE LADDER POWER MODES

There are two power modes, designated as "Mode A" and "Mode B". Mode A is set by the LRLAP<1:0> bits and Mode B by the LRLB<1:0> bits. The resistor ladder to use for Modes A and B are selected by the bits, LRLAP<1:0> and LRLBP<1:0>, respectively.

Each ladder has a matching contrast control ladder, tuned to the nominal resistance of the reference ladder. This contrast control resistor can be controlled by the LCDCST<2:0> bits (LCDREF<5:3>). Disabling the internal reference ladder results in all of the ladders being disconnected, allowing external voltages to be supplied.

To get additional current in High-Power mode, when LRLAP<1:0> (LCDRL<7:6>) = 11, both the medium and high-power resistor ladders are activated.

Whenever the LCD module is inactive, LCDA (LCDPS<5>) = 0), the reference ladder will be turned off.

#### 13.5.1 AUTOMATIC POWER MODE SWITCHING

As an LCD segment is electrically only a capacitor, current is drawn only during the interval when the voltage is switching. To minimize total device current, the LCD reference ladder can be operated in a different power mode for the transition portion of the duration. This is controlled by the LCDREF and LCDRL registers.

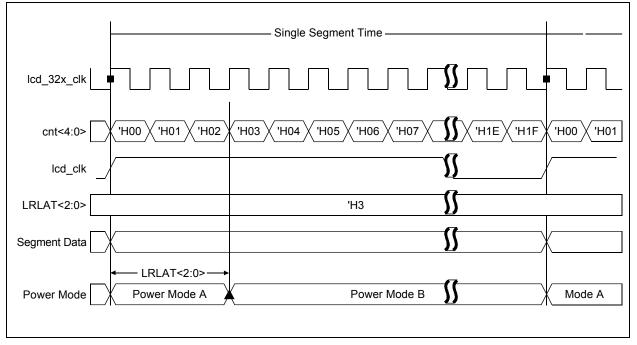

Mode A Power mode is active for a programmable time, beginning at the time when the LCD segment waveform is transitioning. The LRLAT<2:0> bits

(LCDRL<2:0>) select how long or if the Mode A is active. Mode B Power mode is active for the remaining time before the segments or commons change again.

As shown in Figure 13-4, there are 32 counts in a single segment time. Type-A can be chosen during the time when the wave form is in transition. Type-B can be used when the clock is stable or not in transition.

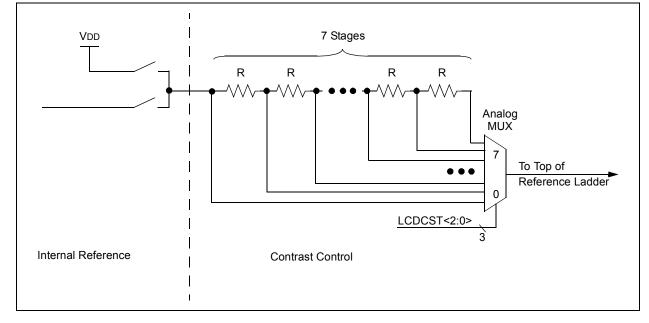

By using this feature of automatic power switching using Type-A/Type-B, the power consumption can be optimized for a given contrast.

#### FIGURE 13-4: LCD REFERENCE LADDER POWER MODE SWITCHING DIAGRAM

### 13.5.2 CONTRAST CONTROL

The LCD contrast control circuit consists of a 7-tap resistor ladder, controlled by the LCDCSTx bits (see Figure 13-5)

#### FIGURE 13-5: INTERNAL REFERENCE AND CONTRAST CONTROL BLOCK DIAGRAM

#### 13.5.3 INTERNAL REFERENCE

Under firmware control, an internal reference for the LCD bias voltages can be enabled. When enabled, the source of this voltage can be VDD.

When no internal reference is selected, the LCD contrast control circuit is disabled and LCD bias must be provided externally. Whenever the LCD module is inactive (LCDA = 0), the internal reference will be turned off.

### 13.5.4 VLCDxPE PINS

The VLCD3PE, VLCD2PE and VLCD1PE pins provide the ability for an external LCD bias network to be used instead of the internal ladder. Use of the VLCDxPE pins does not prevent use of the internal ladder.

Each VLCDxPE pin has an independent control in the LCDREF register, allowing access to any or all of the LCD bias signals.

This architecture allows for maximum flexibility in different applications. The VLCDxPE pins could be used to add capacitors to the internal reference ladder for increasing the drive capacity. For applications where the internal contrast control is insufficient, the firmware can choose to enable only the VLCD3PE pin, allowing an external contrast control circuit to use the internal reference divider.

### 13.5.5 LCD BIAS GENERATION

The LCD driver module is capable of generating the required bias voltages for LCD operation with a minimum of external components. This includes the ability to generate the different voltage levels required by the different bias types that are required by the LCD. The driver module can also provide bias voltages, both above and below microcontroller VDD, through the use of an on-chip LCD voltage regulator.

#### 13.5.6 LCD BIAS TYPES

PIC18F97J94 family devices support three bias types, based on the waveforms generated to control segments and commons:

- Static (two discrete levels)
- 1/2 Bias (three discrete levels)
- 1/3 Bias (four discrete levels)

The use of different waveforms in driving the LCD is discussed in more detail in **Section 13.12 "LCD Waveform Generation**".

### 13.5.7 LCD VOLTAGE REGULATOR

The purpose of the LCD regulator is to provide proper bias voltage and good contrast for the LCD, regardless of VDD levels. This module contains a charge pump and internal voltage reference. The regulator can be configured by using external components to boost bias voltage above VDD. It can also operate a display at a constant voltage below VDD. The regulator can also be selectively disabled to allow bias voltages to be generated by an external resistor network.

The LCD regulator is controlled through the LCDREG register. It is enabled or disabled using the CLKSEL<1:0> bits, while the charge pump can be selectively enabled using the CPEN bit. When the regulator is enabled, the MODE13 bit is used to select the bias type. The peak LCD bias voltage, measured as a difference between the potentials of LCDBIAS3 and LCDBIAS0, is configured with the BIAS bits.

## 13.6 BIAS CONFIGURATIONS

PIC18F97J94 family devices have four distinct circuit configurations for LCD bias generation:

- M0: Regulator with Boost
- M1: Regulator without Boost
- M2: Resistor Ladder with Software Contrast
- · M3: Resistor Ladder with Hardware Contrast

#### 13.6.1 M0 (REGULATOR WITH BOOST)

In M0 operation, the LCD charge pump feature is enabled. This allows the regulator to generate voltages up to +3.6V to the LCD (as measured at LCDBIAS3).

M0 uses a flyback capacitor connected between VLCAP1 and VLCAP2, as well as filter capacitors on LCDBIAS0 through LCDBIAS3, to obtain the required voltage boost (Figure 13-6). The output voltage (VBIAS) is the difference of the potential between LCDBIAS3 and LCDBIAS0. It is set by the BIAS<2:0> bits which adjust the offset between LCDBIAS0 and VSS. The flyback capacitor (CFLY) acts as a charge storage element for large LCD loads. This mode is useful in those cases where the voltage requirements of the LCD are higher than the microcontroller's VDD. It also permits software control of the display's contrast, by adjustment of bias voltage, by changing the value of the BIAS bits.

M0 supports static and 1/3 bias types. Generation of the voltage levels for 1/3 bias is handled automatically, but must be configured in software.

M0 is enabled by selecting a valid regulator clock source (CLKSEL<1:0> set to any value except '00') and setting the CPEN bit. If static bias type is required, the MODE13 bit must be cleared.

### 13.6.2 M1 (REGULATOR WITHOUT BOOST)

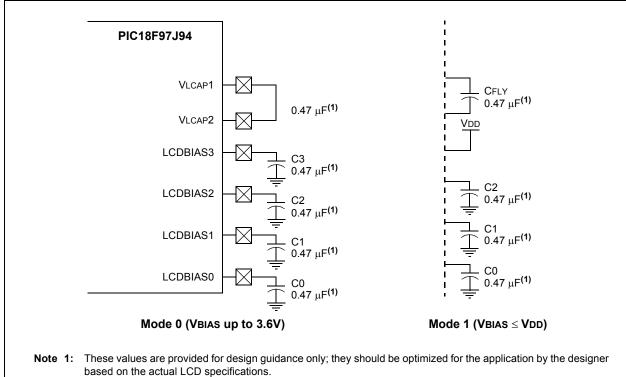

M1 operation is similar to M0, but does not use the LCD charge pump. It can provide VBIAS up to the voltage level supplied directly to LCDBIAS3. It can be used in cases where VDD for the application is expected to never drop below a level that can provide adequate contrast for the LCD. The connection of external components is very similar to M0, except that LCDBIAS3 must be tied directly to VDD (Figure 13-6).

Note:	When the device is put to Sleep while oper-
	ating in mode M0 or M1, make sure that the
	bias capacitors are fully discharged to get
	the lowest Sleep current.

The BIAS<2:0> bits can still be used to adjust contrast in software by changing the VBIAS. As with M0, changing these bits changes the offset between LCDBIAS0 and VSS. In M1, this is reflected in the change between the LCDBIAS0 and the voltage tied to LCDBIAS3. Thus, if VDD should change, VBIAS will also change; where in M0, the level of VBIAS is constant.

Like M0, M1 supports static and 1/3 bias types. Generation of the voltage levels for 1/3 bias is handled automatically but must be configured in software. M1 is enabled by selecting a valid regulator clock source (CLKSEL<1:0> set to any value except '00') and clearing the CPEN bit. If 1/3 bias type is required, the MODE13 bit should also be set.

#### 13.6.3 M2 (EXTERNAL RESISTOR LADDER WITH SOFTWARE CONTRAST)

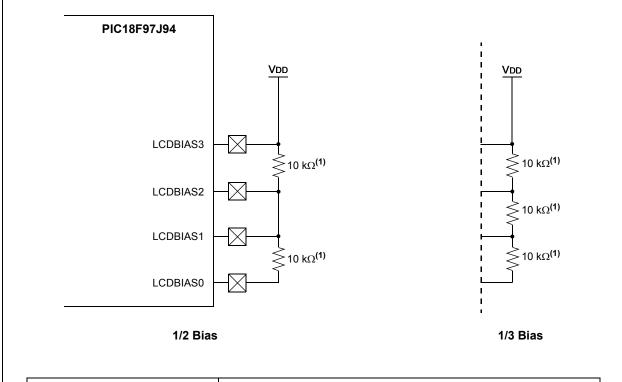

M2 operation also uses the LCD regulator but disables the charge pump. The regulator's internal voltage reference remains active as a way to regulate contrast. It is used in cases where the current requirements of the LCD exceed the capacity of the regulator's charge pump.

In this configuration, the LCD bias voltage levels are created by an external resistor voltage divider, connected across LCDBIAS0 through LCDBIAS3, with the top of the divider tied to VDD (Figure 13-7). The potential at the bottom of the ladder is determined by the LCD regulator's voltage reference, tied internally to

LCDBIAS0. The bias type is determined by the voltages on the LCDBIAS pins, which are controlled by the configuration of the resistor ladder. Most applications, using M2, will use a 1/3 or 1/2 bias type. While static bias can also be used, it offers extremely limited contrast range and additional current consumption over other bias generation modes.

Like M1, the LCDBIAS bits can be used to control contrast, limited by the level of VDD supplied to the device. Also, since there is no capacitor required across VLCAP1 and VLCAP2, these pins are available as digital I/O ports, RG2 and RG3. M2 is selected by clearing the CLKSEL<1:0> bits and setting the CPEN bit.

### FIGURE 13-7: RESISTOR LADDER CONNECTIONS FOR M2 CONFIGURATION

Bias Level at Pin	Bias Type			
Blas Level at Fill	1/2 Bias	1/3 Bias		
LCDBIAS0	(Internal Low Reference Voltage)	(Internal Low Reference Voltage)		
LCDBIAS1	1/2 VBIAS	1/3 VBIAS		
LCDBIAS2	1/2 VBIAS	2/3 VBIAS		
LCDBIAS3	VBIAS (up to VDD)	VBIAS (up to VDD)		

**Note 1:** These values are provided for design guidance only; they should be optimized for the application by the designer based on the actual LCD specifications.

#### 13.6.4 M3 (HARDWARE CONTRAST)

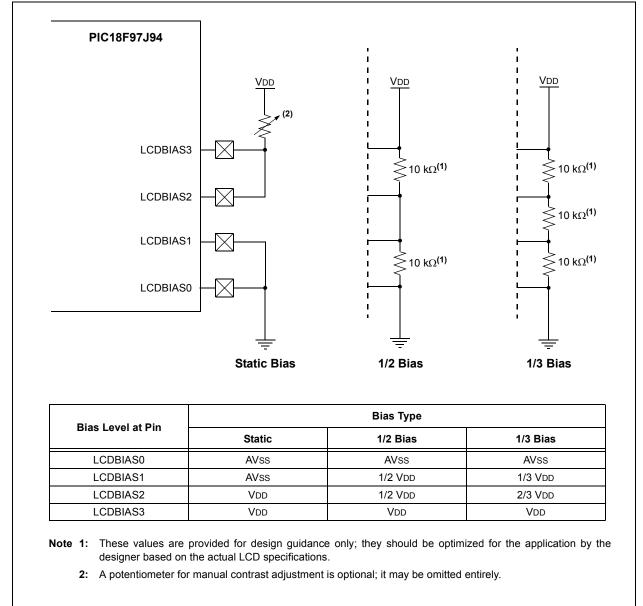

In M3, the LCD regulator is completely disabled. Like M2, LCD bias levels are tied to VDD and are generated using an external divider. The difference is that the internal voltage reference is also disabled and the bottom of the ladder is tied to ground (VSS); see Figure 13-8. The value of the resistors, and the difference between VSS and VDD, determine the contrast range; no software adjustment is possible. This configuration

is also used where the LCD's current requirements exceed the capacity of the charge pump and software contrast control is not needed.

Depending on the bias type required, resistors are connected between some or all of the pins. A potentiometer can also be connected between LCDBIAS3 and VDD to allow for hardware controlled contrast adjustment.

M3 is selected by clearing the CLKSEL<1:0> and CPEN bits.

#### FIGURE 13-8: RESISTOR LADDER CONNECTIONS FOR M3 CONFIGURATION

# 13.7 Design Considerations for the LCD Charge Pump

When designing applications that use the LCD regulator with the charge pump enabled, users must always consider both the dynamic current and RMS (static) current requirements of the display, and what the charge pump can deliver. Both dynamic and static current can be determined by Equation 13-1:

# EQUATION 13-1: LCD STATIC, DYNAMIC CURRENT

$$I = C \times \frac{dV}{dt}$$

For dynamic current, C, is the value of the capacitors attached to LCDBIAS3 and LCDBIAS2. The variable, dV, is the voltage drop allowed on C2 and C3 during a voltage switch on the LCD display, and dt is the duration of the transient current after a clock pulse occurs.

For practical design purposes, it will be assumed to be 0.047  $\mu$ F for C, 0.1V for dV and 1  $\mu$ s for dt. This yields a dynamic current of 4.7 mA for 1  $\mu$ s.

RMS current is determined by the value of CFLY for C, the voltage across VLCAP1 and VLCAP2 for dV and the regulator clock period (TPER) for dt. Assuming a CFLY value of 0.047  $\mu$ F, a value of 1.02V across CFLY and TPER of 30  $\mu$ s, the maximum theoretical static current will be 1.8 mA. Since the charge pump must charge five capacitors, the maximum current becomes 360  $\mu$ A.

For a real-world assumption of 50% efficiency, this yields a practical current of 180  $\mu A.$  Users should compare the calculated current capacity against the

requirements of the LCD. While dV and dt are relatively fixed by device design, the values of CFLY and the capacitors on the LCDBIAS pins can be changed to increase or decrease current. As always, any changes should be evaluated in the actual circuit for their impact on the application.

# 13.8 LCD Multiplex Types

The LCD driver module can be configured into four multiplex types:

- Static (only COM0 used)
- 1/2 multiplex (COM0 and COM1 are used)
- 1/3 multiplex (COM0, COM1 and COM2 are used)
- 1/4 multiplex (COM0, COM1, COM2 and COM3 are used)
- 1/5 multiplex (COM0, COM1, COM2, COM3 and COM4 are used)
- 1/6 multiplex (COM0, COM1, COM2, COM3, COM4 and COM5 are used)
- 1/7 multiplex (COM0, COM1, COM2, COM3, COM4, COM5 and COM6 are used)
- 1/8 multiplex (COM0, COM1, COM2, COM3, COM4, COM5, COM6 and COM7 are used)

The LMUX<2:0> setting (LCDCON<2:0>) decides the function of the COM pins. (For details, see Table 13-4).

If the pin is a digital I/O, the corresponding TRIS bit controls the data direction. If the pin is a COM drive, the TRIS setting of that pin is overridden.

Note:	On a Power-on Reset, the LMUX<2:0>
	bits are '000'.

LMUX<2:0>	COM7 Pin	COM6 Pin	COM5 Pin	COM4 Pin	COM3 Pin	COM2 Pin	COM1 Pin	COM0 Pin
111	COM7	COM6	COM5	COM4	COM3	COM2	COM1	COM0
110	I/O Pin	COM6	COM5	COM4	COM3	COM2	COM1	COM0
101	I/O Pin	I/O Pin	COM5	COM4	COM3	COM2	COM1	COM0
100	I/O Pin	I/O Pin	I/O Pin	COM4	COM3	COM2	COM1	COM0
011	I/O Pin	I/O Pin	I/O Pin	I/O Pin	COM3	COM2	COM1	COM0
010	I/O Pin	COM2	COM1	COM0				
001	I/O Pin	COM1	COM0					
000	I/O Pin	COM0						

TABLE 13-4:	COM<7:0>	PIN FUNCTIONS
-------------	----------	---------------

**Note:** Pins, COM<7:4>, can also be used as SEG pins when ¼ multiplex to static multiplex are used. These pins can be used as I/O pins only if respective bits in the LCDSEx registers are set to '0'.

## 13.9 Segment Enables

The LCDSEx registers are used to select the pin function for each segment pin. The selection allows each pin to operate as either an LCD segment driver or a digital only pin. To configure the pin as a segment pin, the corresponding bits in the LCDSEx registers must be set to '1'. If the pin is a digital I/O, the corresponding TRIS bit controls the data direction. Any bit set in the LCDSEx registers overrides any bit settings in the corresponding TRIS register.

Note: On a Power-on Reset, these pins are configured as digital I/O.

## 13.10 Pixel Control

The LCDDATAx registers contain bits that define the state of each pixel. Each bit defines one unique pixel. Table 13-2 shows the correlation of each bit in the LCDDATAx registers to the respective common and segment signals.

Any LCD pixel location not being used for display can be used as general purpose RAM.

# 13.11 LCD Frame Frequency

The rate at which the COM and SEG outputs change is called the LCD frame frequency.

TABLE 13-5:	FRAME FREQUENCY FORMULAS
-------------	--------------------------

Multiplex	Frame Frequency =
Static ('000')	Clock Source/(4 x 1 x (LP<3:0> + 1))
1/2 ('001')	Clock Source/(2 x 2 x (LP<3:0> + 1))
1/3 ('010')	Clock Source/(1 x 3 x (LP<3:0> + 1))
1/4 ('011')	Clock Source/(1 x 4 x (LP<3:0> + 1))
1/5 ('100')	Clock Source/(1 x 5 x (LP<3:0> + 1))
1/6 ('101')	Clock Source/(1 x 6 x (LP<3:0> + 1))
1/7 ('110')	Clock Source/(1 x 7 x (LP<3:0> + 1))
1/8 ('111')	Clock Source/(1 x 8 x (LP<3:0> + 1))

**Note:** The clock source is FRC/8192, SOSC/32 or LPRC/32.

## 13.12 LCD Waveform Generation

LCD waveform generation is based on the philosophy that the net AC voltage across the dark pixel should be maximized and the net AC voltage across the clear pixel should be minimized. The net DC voltage across any pixel should be zero.

The COM signal represents the time slice for each common, while the SEG contains the pixel data.

The pixel signal (COM-SEG) will have no DC component and can take only one of the two rms values. The higher rms value will create a dark pixel and a lower rms value will create a clear pixel.

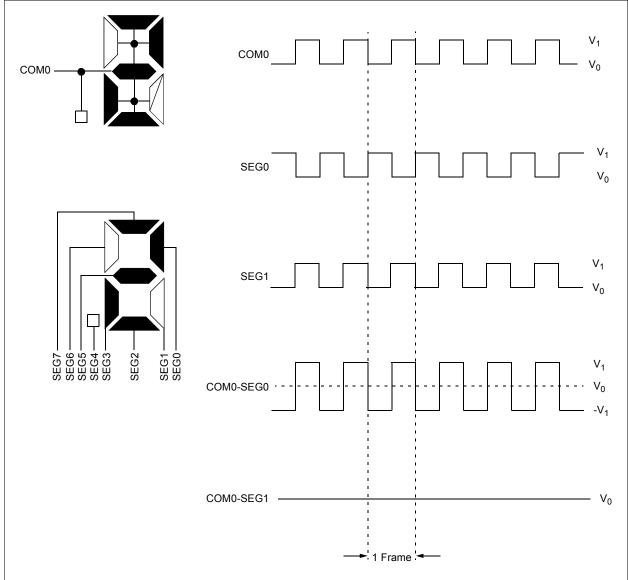

As the number of commons increases, the delta between the two rms values decreases. The delta represents the maximum contrast that the display can have.

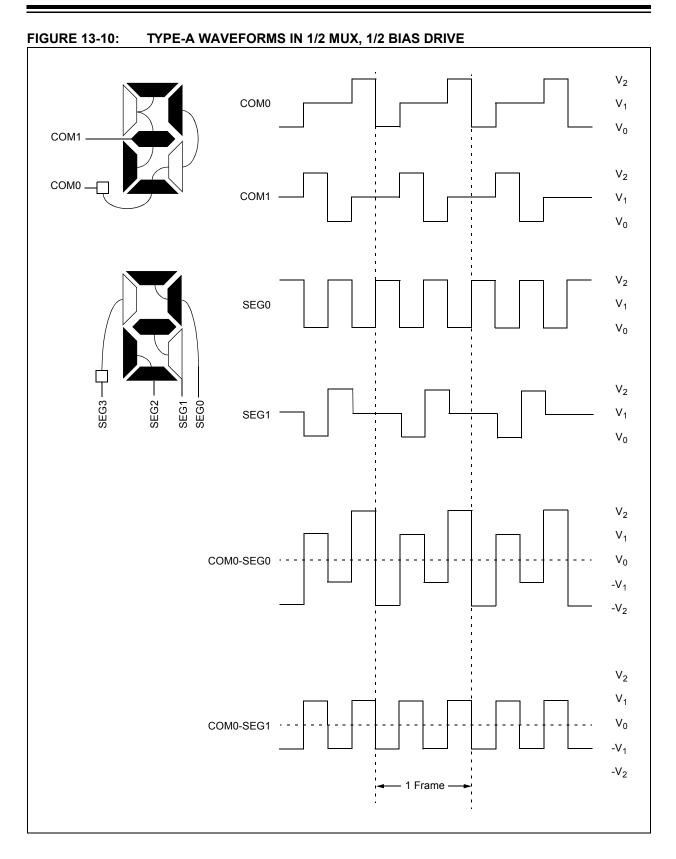

The LCDs can be driven by two types of waveforms: Type-A and Type-B. In a Type-A waveform, the phase changes within each common type, whereas a Type-B waveform's phase changes on each frame boundary. Thus, Type-A waveforms maintain 0 VDC over a single frame, whereas Type-B waveforms take two frames.

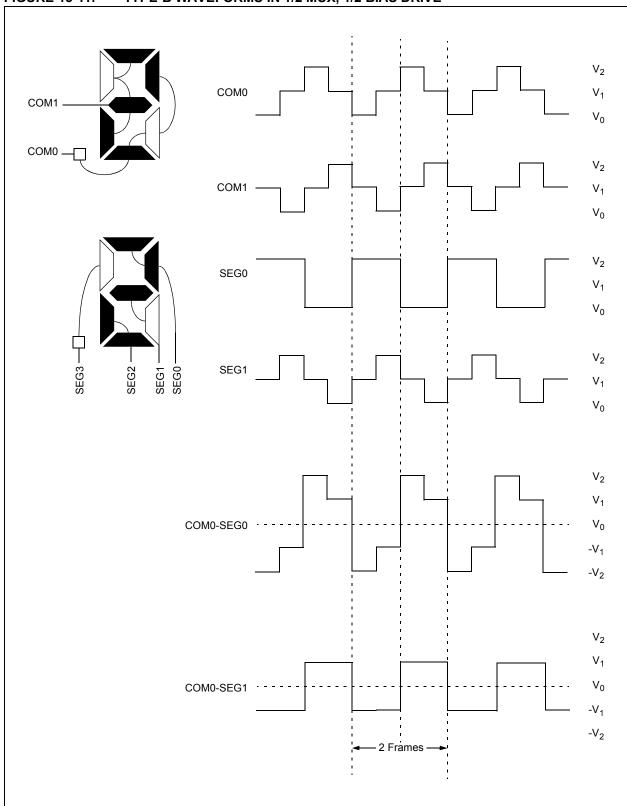

Note: If Sleep has to be executed with LCD Sleep enabled (SLPEN (LCDCON<6>) = 1), care must be taken to execute Sleep only when VDC on all the pixels is '0'.

Figure 13-9 through Figure 13-21 provide waveforms for static, half-multiplex, one-third multiplex and quarter multiplex drives for Type-A and Type-B waveforms.

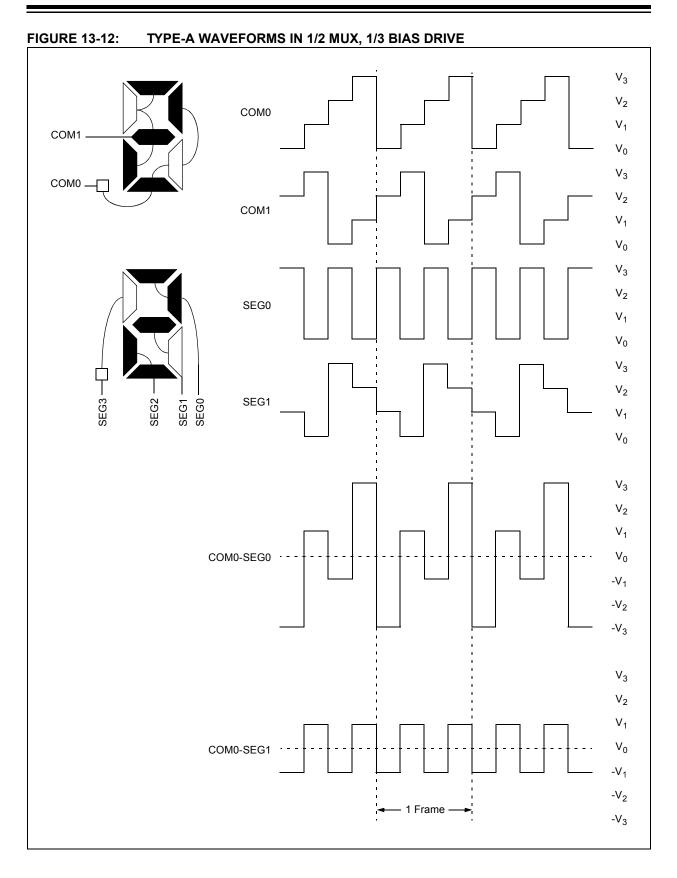

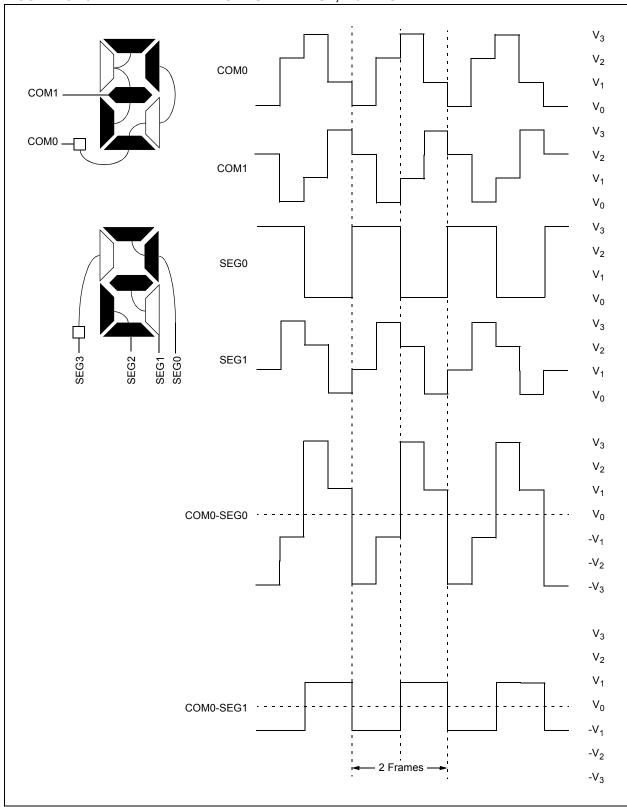

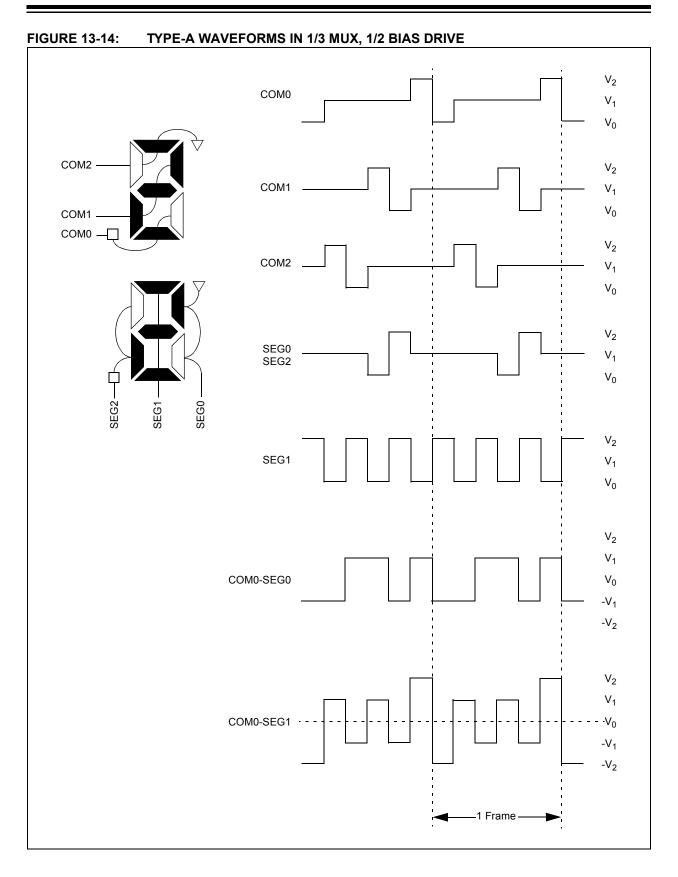

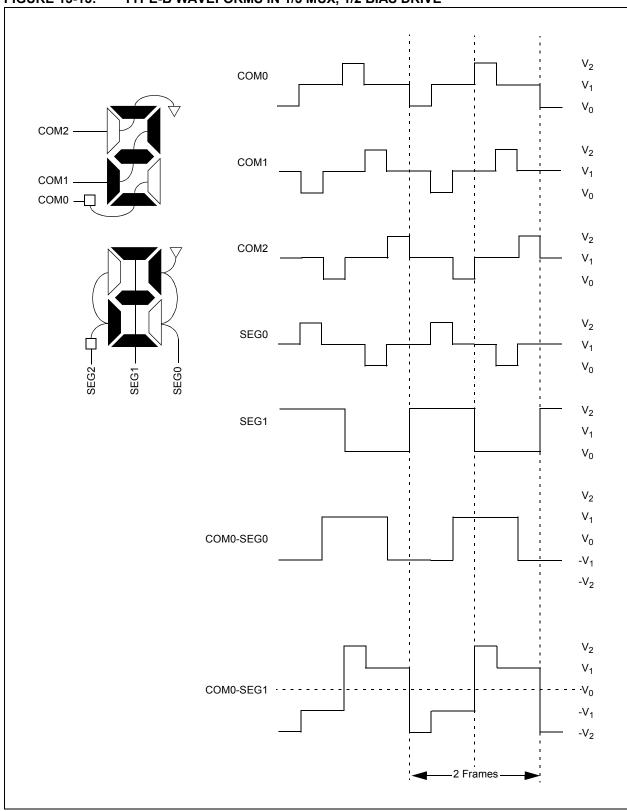

### FIGURE 13-11: TYPE-B WAVEFORMS IN 1/2 MUX, 1/2 BIAS DRIVE

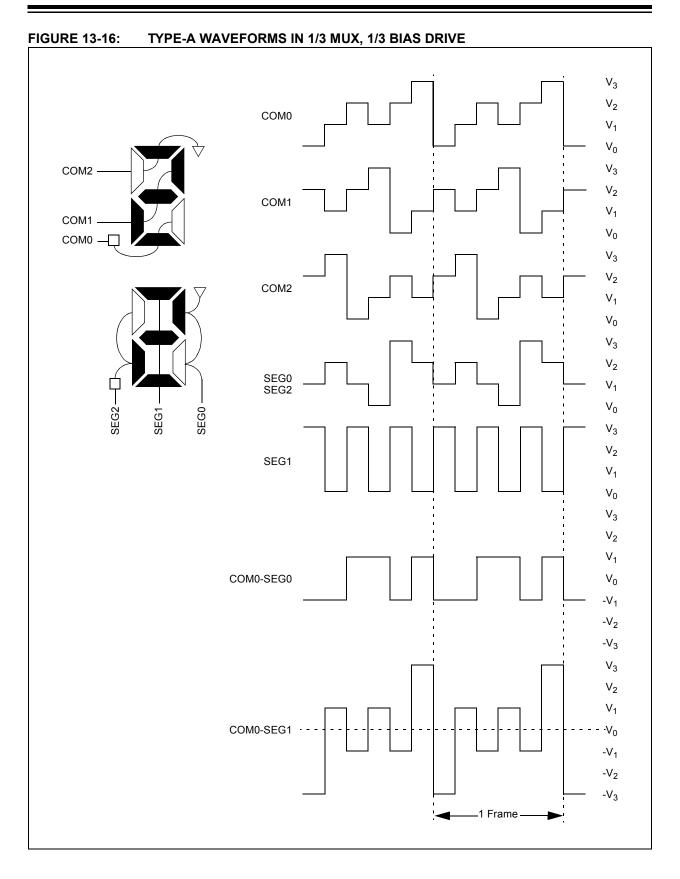

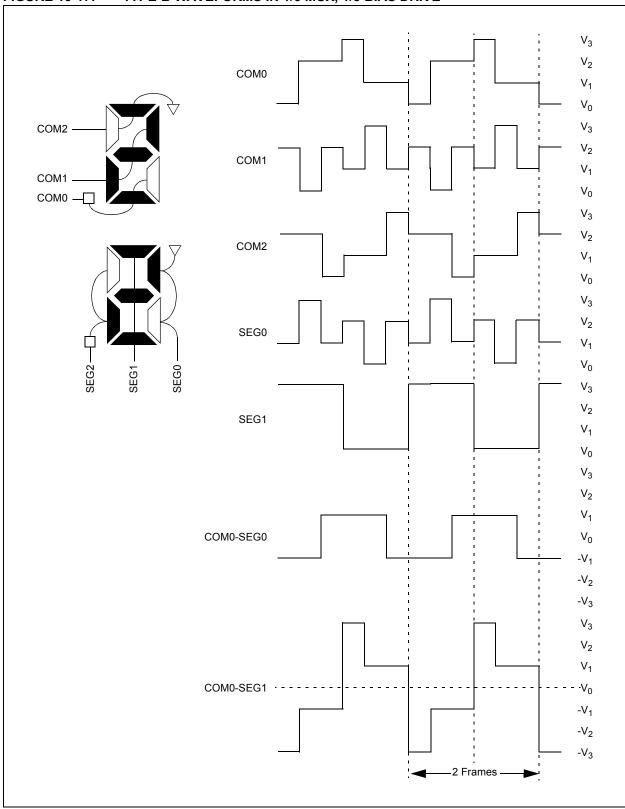

### FIGURE 13-13: TYPE-B WAVEFORMS IN 1/2 MUX, 1/3 BIAS DRIVE

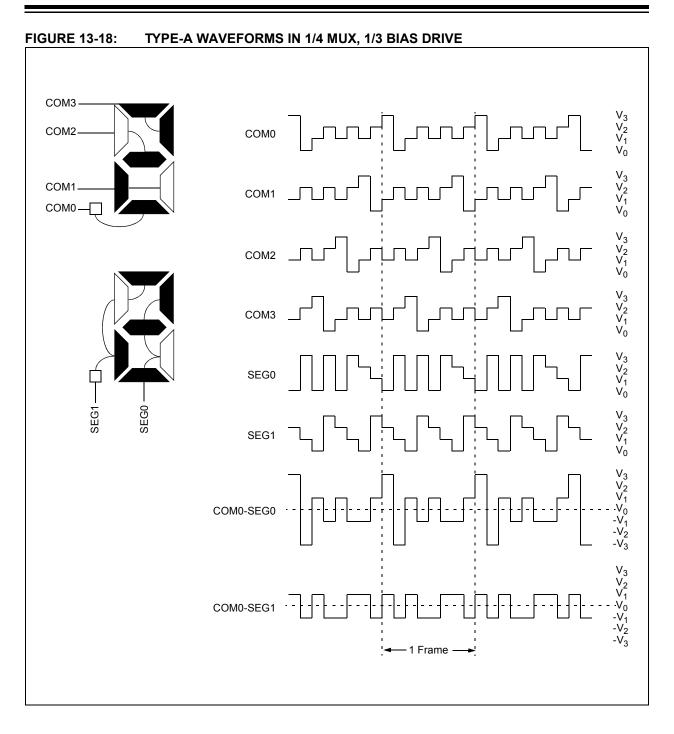

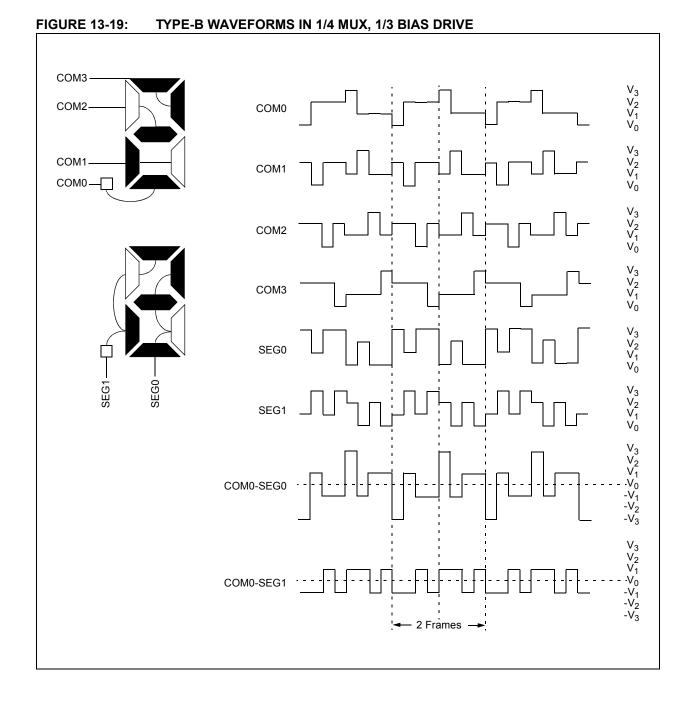

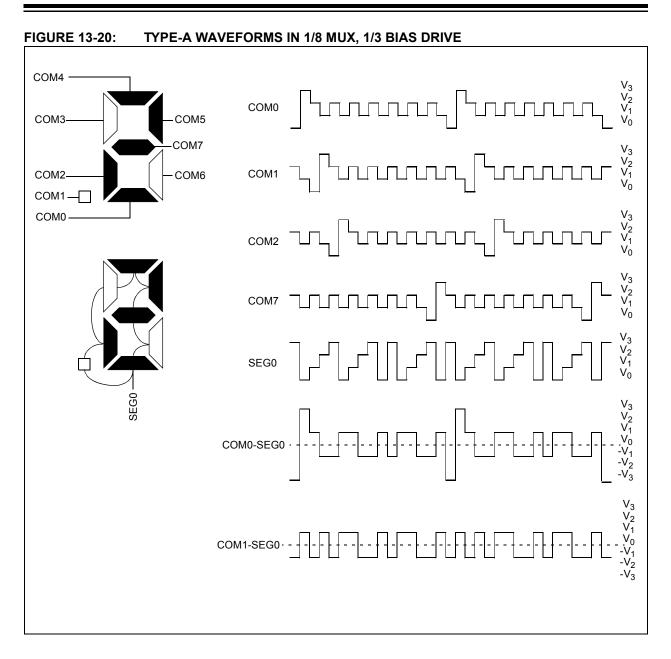

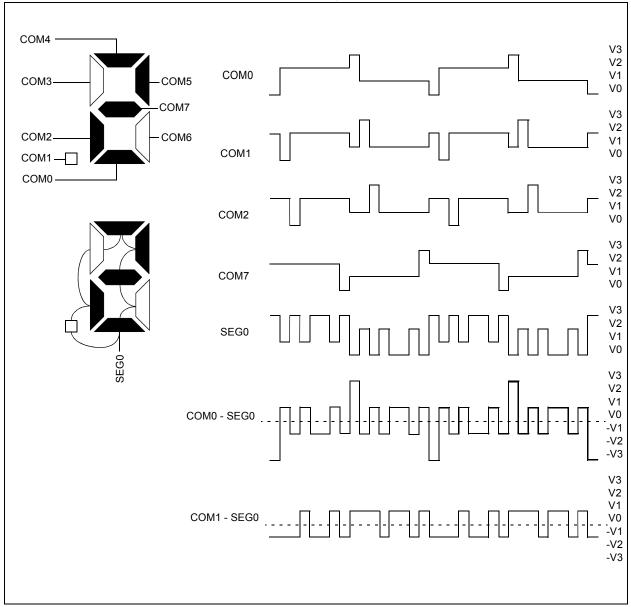

### FIGURE 13-17: TYPE-B WAVEFORMS IN 1/3 MUX, 1/3 BIAS DRIVE

# FIGURE 13-21: TYPE-B WAVEFORMS IN 1/8 MUX, 1/3 BIAS DRIVE

### 13.13 LCD Interrupts

The LCD timing generation provides an interrupt that defines the LCD frame timing. This interrupt can be used to coordinate the writing of the pixel data with the start of a new frame, which produces a visually crisp transition of the image.

This interrupt can also be used to synchronize external events to the LCD. For example, the interface to an external segment driver can be synchronized for segment data updates to the LCD frame.

A new frame is defined as beginning at the leading edge of the COM0 common signal. The interrupt will be set immediately after the LCD controller completes accessing all pixel data required for a frame. This will occur at a fixed interval before the frame boundary (TFINT), as shown in Figure 13-22.

The LCD controller will begin to access data for the next frame within the interval from the interrupt to when the controller begins accessing data after the interrupt (TFWR). New data must be written within TFWR, as this is when the LCD controller will begin to access the data for the next frame.

When the LCD driver is running with Type-B waveforms, and the LMUX<2:0> bits are not equal to '000', there are some additional issues.

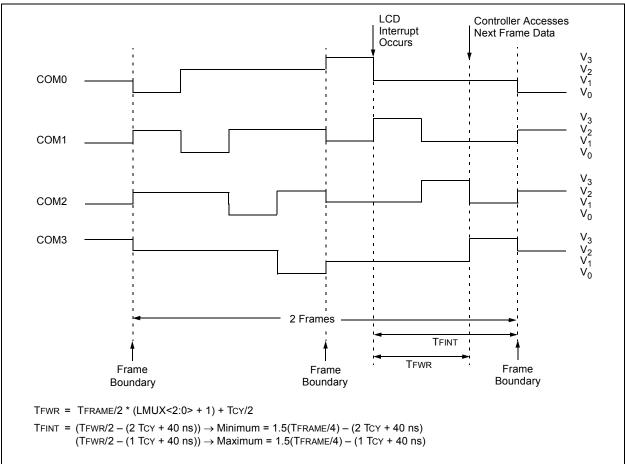

Since the DC voltage on the pixel takes two frames to maintain 0V, the pixel data must not change between subsequent frames. If the pixel data were allowed to change, the waveform for the odd frames would not necessarily be the complement of the waveform generated in the even frames and a DC component would be introduced into the panel.

Because of this, using Type-B waveforms requires synchronizing the LCD pixel updates to occur within a subframe after the frame interrupt.

To correctly sequence writing in Type-B, the interrupt only occurs on complete phase intervals. If the user attempts to write when the write is disabled, the WERR bit (LCDCON<5>) is set.

**Note:** The interrupt is not generated when the Type-A waveform is selected and when the Type-B with no multiplex (static) is selected.

FIGURE 13-22: EXAMPLE WAVEFORMS AND INTERRUPT TIMING IN QUARTER DUTY CYCLE DRIVE

## 13.14 Configuring the LCD Module

To configure the LCD module.

- 1. Select the frame clock prescale using bits, LP<3:0> (LCDPS<3:0>).
- 2. Configure the appropriate pins to function as segment drivers using the LCDSEx registers.
- If using the internal reference resistors for biasing, enable the internal reference ladder and:
  - Define the Mode A and Mode B interval by using the LRLAT<2:0> bits (LCDRL<2:0>)
  - Define the low, medium or high ladder for Mode A and Mode B by using the LRLAP<1:0> bits (LCDRL<7:6>) and the LRLBP<1:0> bits (LCDRL<5:4>), respectively
  - Set the VLCDxPE bits and enable the LCDIRE bit (LCDREF<7>)
- 4. Configure the following LCD module functions using the LCDCON register:
  - Multiplex and Bias mode LMUX<2:0> bits
  - Timing Source CS<1:0> bits
  - Sleep mode SLPEN bit
- 5. Write initial values to the Pixel Data registers, LCDDATA0 through LCDDATA63.
- 6. Clear the LCD Interrupt Flag, LCDIF, and if desired, enable the interrupt by setting bit, LCDIE.
- Enable the LCD module by setting the LCDEN bit (LCDCON<7>)

## 13.15 Operation During Sleep

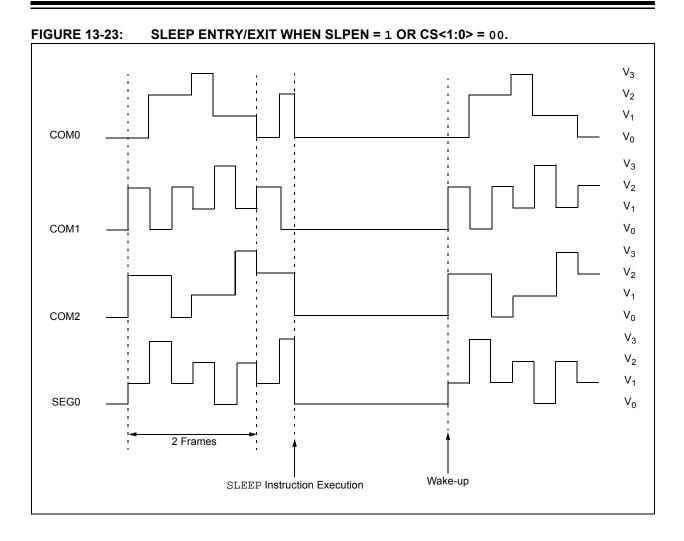

The LCD module can operate during Sleep. The selection is controlled by the SLPEN bit (LCDCON<6>). Setting the SLPEN bit allows the LCD module to go to Sleep. Clearing the SLPEN bit allows the module to continue to operate during Sleep.

If a SLEEP instruction is executed and SLPEN = 1, the LCD module will cease all functions and go into a very Low-Current Consumption mode. The module will stop operation immediately and drive the minimum LCD voltage on both segment and common lines. Figure 13-23 shows this operation.

The LCD module current consumption will not decrease in this mode, but the overall consumption of the device will be lower due to shut down of the core and other peripheral functions.

To ensure that no DC component is introduced on the panel, the SLEEP instruction should be executed immediately after an LCD frame boundary. The LCD interrupt can be used to determine the frame boundary. See **Section 13.13 "LCD Interrupts**" for the formulas to calculate the delay.

If a SLEEP instruction is executed and SLPEN = 0, the module will continue to display the current contents of the LCDDATA registers. The LCD data cannot be changed.

# 14.0 TIMER0 MODULE

The Timer0 module incorporates the following features:

- Software-selectable operation as a timer or counter in both 8-bit or 16-bit modes
- · Readable and writable registers
- Dedicated 8-bit, software programmable
   prescaler
- · Selectable clock source (internal or external)
- Edge select for external clock
- Interrupt-on-overflow

The T0CON register (Register 14-1) controls all aspects of the module's operation, including the prescale selection. It is both readable and writable.

Figure 14-1 provides a simplified block diagram of the Timer0 module in 8-bit mode. Figure 14-2 provides a simplified block diagram of the Timer0 module in 16-bit mode.

## 14.1 Timer0 Operation

Timer0 can operate in one of these two modes:

- As an 8-bit (T08BIT = 1) or 16-bit (T08BIT = 0) timer
- As an asynchronous 8-bit (T08BIT = 1) or 16-bit (T08BIT = 0) counter

#### 14.1.1 TIMER MODE

In Timer mode, Timer0 either increments every CPU clock cycle, or every instruction cycle, depending on the clock select bit, TMR0CS<1:0> (T0CON<7:6>).

#### 14.1.2 COUNTER MODE

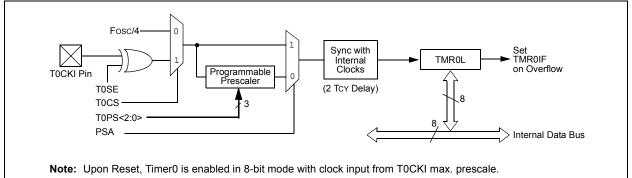

In this mode, Timer0 is incremented via a rising or falling edge of an external source on the T0CKI pin. The clock select bits, TMR0CS<1:0>, must be set to '1x'.

# 14.2 Timer0 Reads and Writes in 16-Bit Mode

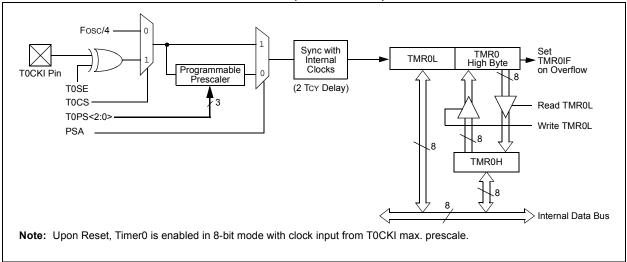

TMR0H is not the actual high byte of Timer0 in 16-bit mode. It is actually a buffered version of the real high byte of Timer0, which is not directly readable nor writable (see Figure 14-2). TMR0H is updated with the contents of the high byte of Timer0 during a read of TMR0L. This provides the ability to read all 16 bits of Timer0 without having to verify that the read of the high and low byte were valid, due to a rollover between successive reads of the high and low byte.

Similarly, a write to the high byte of Timer0 must also take place through the TMR0H Buffer register. The high byte is updated with the contents of TMR0H when a write occurs to TMR0L. This allows all 16 bits of Timer0 to be updated at once.

#### FIGURE 14-2: TIMER0 BLOCK DIAGRAM (16-BIT MODE)

### 14.3 Prescaler

An 8-bit counter is available as a prescaler for the Timer0 module. The prescaler is not directly readable or writable. Its value is set by the PSA and T0PS<2:0> bits (T0CON<3:0>), which determine the prescaler assignment and prescale ratio.

Clearing the PSA bit assigns the prescaler to the Timer0 module. When it is assigned, prescale values from 1:2 through 1:256 in power-of-two increments are selectable.

When assigned to the Timer0 module, all instructions writing to the TMR0 register (for example, CLRF TMR0, MOVWF TMR0, BSF TMR0) clear the prescaler count.

**Note:** Writing to TMR0 when the prescaler is assigned to Timer0 will clear the prescaler count but will not change the prescaler assignment.

#### 14.3.1 SWITCHING PRESCALER ASSIGNMENT

The prescaler assignment is fully under software control and can be changed "on-the-fly" during program execution.

### 14.4 Timer0 Interrupt

The TMR0 interrupt is generated when the TMR0 register overflows from FFh to 00h in 8-bit mode, or from FFFFh to 0000h in 16-bit mode. This overflow sets the TMR0IF flag bit. The interrupt can be masked by clearing the TMR0IE bit (INTCON<5>). Before reenabling the interrupt, the TMR0IF bit must be cleared in software by the Interrupt Service Routine (ISR).

Since Timer0 is shutdown in Sleep mode, the TMR0 interrupt cannot awaken the processor from Sleep.

# 15.0 TIMER1/3/5 MODULES

The Timer1/3/5 timer/counter modules incorporate these features:

- Software-selectable operation as a 16-bit timer or counter
- Readable and writable 8-bit registers (TMRxH and TMRxL)
- Selectable clock source (internal or external) with device clock or SOSC Oscillator internal options
- Interrupt-on-overflow
- Module Reset on ECCP Special Event Trigger

**Note:** Throughout this section, generic references are used for register and bit names that are the same – except for an 'x' variable that indicates the item's association with the Timer1, Timer3 or Timer5 module. For example, the control register is named TxCON and refers to T1CON, T3CON and T5CON.

A simplified block diagram of the Timer1/3/5 module is shown in Figure 15-1.

The Timer1/3/5 module is controlled through the TxCON register (Register 15-1). It also selects the clock source options for the ECCP modules. (For more information, see Section 18.1.1 "ECCP Module and Timer Resources").

The FOSC clock source should not be used with the ECCP capture/compare features. If the timer will be used with the capture or compare features, always select one of the other timer clocking options.

## 15.1 Timer1/3/5 Gate Control Register

The Timer1/3/5 Gate Control register (TxGCON), provided in Register 15-2, is used to control the Timerx gate.

#### REGISTER 15-2: TxGCON: TIMERx GATE CONTROL REGISTER<sup>(1)</sup>

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R-x	R/W-0	R/W-0
TMRxGE	TxGPOL	TxGTM	TxGSPM	TxGGO/TxDONE	TxGVAL	TxGSS1	TxGSS0
bit 7				· · ·			bit 0

Legend:			
R = Readable bit	W = Writable bit	U = Unimplemented bit, r	read as '0'
-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

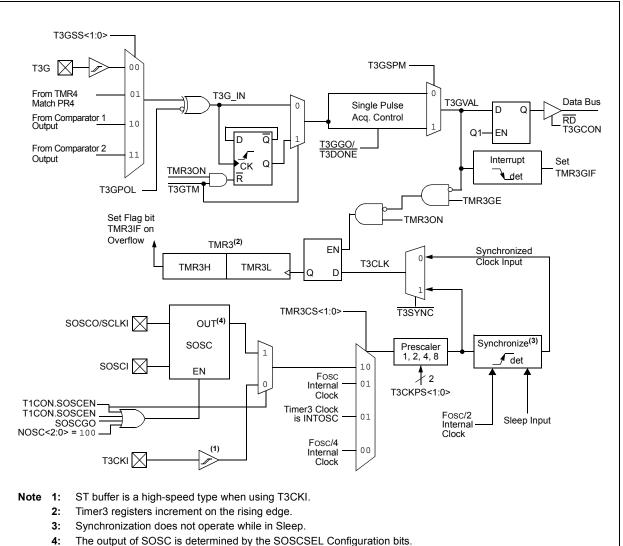

bit 7	TMRxGE: Timerx Gate Enable bit
	<u>If TMRxON = 0:</u>
	This bit is ignored.
	<u>If TMRxON = 1:</u>
	1 = Timerx counting is controlled by the Timerx gate function
	0 = Timerx counts regardless of Timerx gate function
bit 6	TxGPOL: Timerx Gate Polarity bit
	<ul> <li>1 = Timerx gate is active-high (Timerx counts when gate is high)</li> <li>0 = Timerx gate is active-low (Timerx counts when gate is low)</li> </ul>
bit 5	TxGTM: Timerx Gate Toggle Mode bit
	1 = Timerx Gate Toggle mode is enabled.
	0 = Timerx Gate Toggle mode is disabled and toggle flip-flop is cleared
	Timerx gate flip-flop toggles on every rising edge.
bit 4	TxGSPM: Timerx Gate Single Pulse Mode bit
	<ul> <li>1 = Timerx Gate Single Pulse mode is enabled and is controlling Timerx gate</li> <li>0 = Timerx Gate Single Pulse mode is disabled</li> </ul>

	1 = Timerx gate single pulse acquisition is ready, waiting for an edge
	0 = Timerx gate single pulse acquisition has completed or has not been started
	This bit is automatically cleared when TxGSPM is cleared.
bit 2	TxGVAL: Timerx Gate Current State bit
	Indicates the current state of the Timerx gate that could be provided to TMRxH:TMRxL; unaffected by the Timerx Gate Enable (TMRxGE) bit.
bit 1-0	TxGSS<1:0>: Timerx Gate Source Select bits
	11 = Comparator 2 output
	10 = Comparator 1 output
	01 = TMR(x+1) to match PR(x+1) output <sup>(2)</sup>
	00 = Timer1 gate pin The Watchdog Timer Oscillator is turned on if TMRxGE = 1, regardless of the state of TMRxON.
Note to	
Note 1:	Programming the TxGCON prior to TxCON is recommended

2: Timer(x+1) will be Timer1/3/5 for Timerx (Timer1/3/5), respectively.

## 15.2 Timer1/3/5 Operation

Timer1, Timer3 and Timer5 can operate in these modes:

- Timer
- Synchronous Counter
- Asynchronous Counter
- · Timer with Gated Control

## FIGURE 15-1: TIMER1/3/5 BLOCK DIAGRAM

The operating mode is determined by the clock select bits, TMRxCSx (TxCON<7:6>). When the TMRxCSx bits are cleared (= 00), Timer1/3/5 increments on every internal instruction cycle (FOSC/4). When TMRxCSx = 01, the Timer1/3/5 clock source is the system clock (FOSC). When it is '10', Timer1/3/5 works as a counter from the external clock from the TxCKI pin (on the rising edge after the first falling edge) or the SOSC Oscillator. When it is '11', the Timer1/3/5 clock source is INTOSC.

### 15.3 Timer1/3/5 16-Bit Read/Write Mode

Timer1/3/5 can be configured for 16-bit reads and writes (see Figure 15-3). When the RD16 control bit (TxCON<1>) is set, the address for TMRxH is mapped to a buffer register for the high byte of Timer1/3/5. A read from TMRxL will load the contents of the high byte of Timer1/3/5 into the Timerx High Byte Buffer register. This provides users with the ability to accurately read all 16 bits of Timer1/3/5 without having to determine whether a read of the high byte, followed by a read of the low byte, has become invalid due to a rollover between reads.

A write to the high byte of Timer1/3/5 must also take place through the TMRxH Buffer register. The Timer1/3/5 high byte is updated with the contents of TMRxH when a write occurs to TMRxL. This allows users to write all 16 bits to both the high and low bytes of Timer1/3/5 at once.

The high byte of Timer1/3/5 is not directly readable or writable in this mode. All reads and writes must take place through the Timerx High Byte Buffer register.

Writes to TMRxH do not clear the Timer1/3/5 prescaler. The prescaler is only cleared on writes to TMRxL.

### 15.4 Using the SOSC Oscillator as the Timer1/3/5 Clock Source

The SOSC Internal Oscillator may be used as the clock source for Timer1/3/5. It can be enabled in one of these ways:

- Setting the SOSCEN bit in either of the TxCON registers (TxCON<3>)
- Setting the SOSCGO bit in the OSCCON2 register (OSCCON2<1>)
- Setting the NOSC bits to secondary clock source in the OSCCON register (OSCCON<2:0> = 100)

The SOSCGO bit is used to warm up the SOSC so that it is ready before any peripheral requests it.

To use it as the Timer3 clock source, the TMR3CSx bits must also be set. As previously noted, this also configures Timer3 to increment on every rising edge of the oscillator source.

The SOSC Oscillator is described in Section 15.4 "Using the SOSC Oscillator as the Timer1/3/5 Clock Source".

### 15.5 Timer1/3/5 Gates

Timer1/3/5 can be configured to count freely or the count can be enabled and disabled using the Timer1/3/5 gate circuitry. This is also referred to as the Timer1/3/5 gate count enable.

The Timer1/3/5 gate can also be driven by multiple selectable sources.

### 15.5.1 TIMER1/3/5 GATE COUNT ENABLE

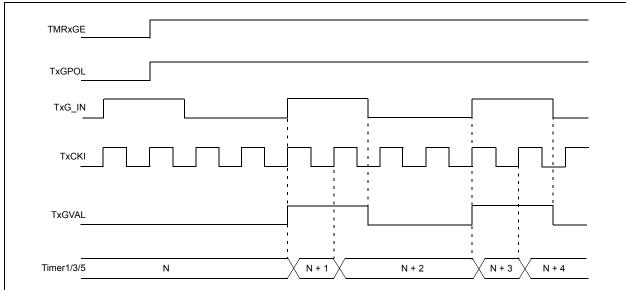

The Timerx Gate Enable mode is enabled by setting the TMRxGE bit (TxGCON<7>). The polarity of the Timerx Gate Enable mode is configured using the TxGPOL bit (TxGCON<6>).

When Timerx Gate Enable mode is enabled, Timer1/3/5 will increment on the rising edge of the Timer1/3/5 clock source. When Timerx Gate Enable mode is disabled, no incrementing will occur and Timer1/3/5 will hold the current count. See Figure 15-2 for timing details.

TABLE 15-1:	TIMER1/3/5 GATE ENABLE
	SELECTIONS

TxCLK <sup>(†)</sup>	TxGPOL (TxGCON<6>)	TxG Pin	Timerx Operation
1	0	0	Counts
$\uparrow$	0	1	Holds Count
$\uparrow$	1	0	Holds Count
$\uparrow$	1	1	Counts

† The clock on which TMR1/3/5 is running. For more information, see TxCLK in Figure 15-1.

### FIGURE 15-2: TIMER1/3/5 GATE COUNT ENABLE MODE

#### 15.5.2 TIMER1/3/5 GATE SOURCE SELECTION

The Timer1/3/5 gate source can be selected from one of four different sources. Source selection is controlled by the TxGSS<1:0> bits (TxGCON<1:0>). The polarity for each available source is also selectable and is controlled by the TxGPOL bit (TxGCON <6>).

TABLE 15-2:	<b>TIMER1/3/5 GATE SOURCES</b>	
		4

TxGSS<1:0>	Timerx Gate Source
00	Timerx Gate Pin
01	TMR(x+1) to Match PR(x+1) (TMR(x+1) increments to match PR(x+1))
10	Comparator 1 Output (comparator logic high output)
11	Comparator 2 Output (comparator logic high output)

#### 15.5.2.1 TxG Pin Gate Operation

The TxG pin is one source for Timer1/3/5 gate control. It can be used to supply an external source to the Timerx gate circuitry.

#### 15.5.2.2 Timer2/4/6/8 Match Gate Operation

The TMR(x+1) register will increment until it matches the value in the PR(x+1) register. On the very next increment cycle, TMR2 will be reset to 00h. When this Reset occurs, a low-to-high pulse will automatically be generated and internally supplied to the Timerx gate circuitry. The pulse will remain high for one instruction cycle and will return back to a low state until the next match.

Depending on TxGPOL, Timerx increments differently when TMR(x+1) matches PR(x+1). When TxGPOL = 1, Timerx increments for a single instruction cycle following a TMR(x+1) match with PR(x+1). When TxGPOL = 0, Timerx increments continuously, except for the cycle following the match, when the gate signal goes from low-to-high.

#### 15.5.2.3 Comparator 1 Output Gate Operation

The output of Comparator1 can be internally supplied to the Timerx gate circuitry. After setting up Comparator 1 with the CM1CON register, Timerx will increment depending on the transitions of the C1OUT (CMSTAT<0>) bit.

#### 15.5.2.4 Comparator 2 Output Gate Operation

The output of Comparator 2 can be internally supplied to the Timerx gate circuitry. After setting up Comparator 2 with the CM2CON register, Timerx will increment depending on the transitions of the C2OUT (CMSTAT<1>) bit.

#### 15.5.3 TIMER1/3/5 GATE TOGGLE MODE

When Timer1/3/5 Gate Toggle mode is enabled, it is possible to measure the full cycle length of a Timer1/3/5 gate signal, as opposed to the duration of a single level pulse.

The Timerx gate source is routed through a flip-flop that changes state on every incrementing edge of the signal. (For timing details, see Figure 15-3.)

The TxGVAL bit will indicate when the Toggled mode is active and the timer is counting.

Timer1/3/5 Gate Toggle mode is enabled by setting the TxGTM bit (TxGCON<5>). When the TxGTM bit is cleared, the flip-flop is cleared and held clear. This is necessary in order to control which edge is measured.

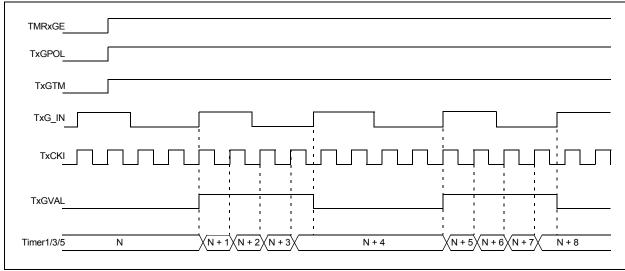

FIGURE 15-3: TIMER1/3/5 GATE TOGGLE MODE

#### 15.5.4 TIMER1/3/5 GATE SINGLE PULSE MODE

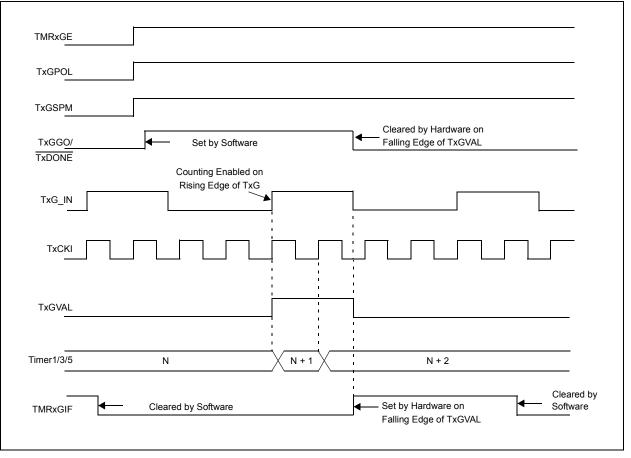

When Timer1/3/5 Gate Single Pulse mode is enabled, it is possible to capture a single pulse gate event. Timer1/3/5 Gate Single Pulse mode is first enabled by setting the TxGSPM bit (TxGCON<4>). Next, the TxGGO/ TxDONE bit (TxGCON<3>) must be set.

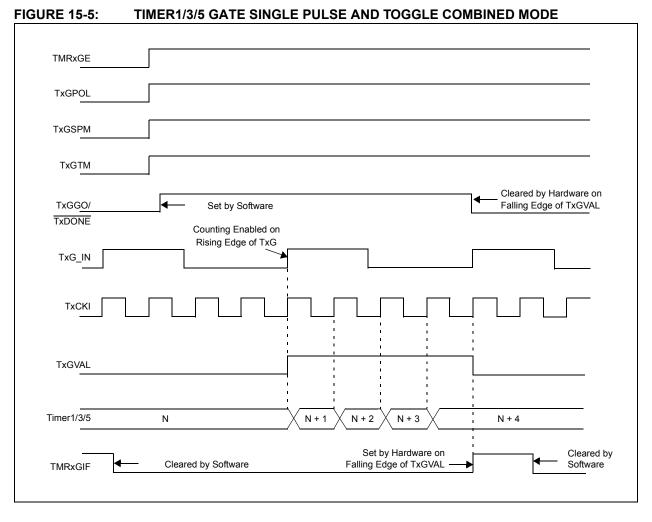

The Timer1/3/5 will be fully enabled on the next incrementing edge. On the next trailing edge of the pulse, the TxGGO/TxDONE bit will automatically be cleared. No other gate events will <u>be allowed</u> to increment Timer1/3/5 until the TxGGO/TxDONE bit is once again set in software.

<u>Clearing</u> the TxGSPM bit also will clear the TxGGO/ TxDONE bit. (For timing details, see Figure 15-4.)

Simultaneously enabling the Toggle mode and the Single Pulse mode will permit both sections to work together. This allows the cycle times on the Timer1/3/5 gate source to be measured. (For timing details, see Figure 15-5.)

# FIGURE 15-4: TIMER1/3/5 GATE SINGLE PULSE MODE

# 15.5.5 TIMER1/3/5 GATE VALUE STATUS

When Timer1/3/5 gate value status is utilized, it is possible to read the most current level of the gate control value. The value is stored in the TxGVAL bit (TxGCON<2>). The TxGVAL bit is valid even when the Timer1/3/5 gate is not enabled (TMRxGE bit is cleared).

#### 15.5.6 TIMER1/3/5 GATE EVENT INTERRUPT

When the Timer1/3/5 gate event interrupt is enabled, it is possible to generate an interrupt upon the completion of a gate event. When the falling edge of TxGVAL occurs, the TMRxGIF flag bit in the PIRx register will be set. If the TMRxGIE bit in the PIEx register is set, then an interrupt will be recognized.

The TMRxGIF flag bit operates even when the Timer1/3/5 gate is not enabled (TMRxGE bit is cleared).

# 15.6 Timer1/3/5 Interrupt

The TMRx register pair (TMRxH:TMRxL) increments from 0000h to FFFFh and overflows to 0000h. The Timerx interrupt, if enabled, is generated on overflow and is latched in the interrupt flag bit, TMRxIF. Table 15-3 gives each module's flag bit.

#### TABLE 15-3: TIMER1/3/5 INTERRUPT FLAG BITS

Timer Module	Flag Bit
1	PIR1<0>
3	PIR2<1>
5	PIR5<1>

This interrupt can be enabled or disabled by setting or clearing the TMRxIE bit, respectively. Table 15-4 gives each module's enable bit.

#### TABLE 15-4: TIMER1/3/5 INTERRUPT ENABLE BITS

Timer Module	Flag Bit
1	PIE1<0>
3	PIE2<1>
5	PIE5<1>

# 15.7 Resetting Timer1/3/5 Using the ECCP Special Event Trigger

If the ECCP modules are configured to use Timerx and to generate a Special Event Trigger in Compare mode (CCPxM<3:0> = 1011), this signal will reset Timerx. The trigger from ECCP2 will also start an A/D conversion if the A/D module is enabled (For more information, see **Section 18.3.4 "Special Event Trigger**".)

The module must be configured as either a timer or synchronous counter to take advantage of this feature. When used this way, the CCPRxH:CCPRxL register pair effectively becomes a Period register for Timerx.

If Timerx is running in Asynchronous Counter mode, the Reset operation may not work.

In the event that a write to Timerx coincides with a Special Event Trigger from an ECCP module, the write will take precedence.

Note:	The Special Event Triggers from the
	ECCPx module will only clear the TMR3
	register's content, but not set the TMR3IF
	interrupt flag bit (PIR1<0>).

Note: The CCP and ECCP modules use Timers, 1 through 8, for some modes. The assignment of a particular timer to a CCP/ECCP module is determined by the Timer to CCP enable bits in the CCPTMRSx registers. For more details, see Register 18-2, Register 18-3 and Register 19-2

# 16.0 TIMER2/4/6/8 MODULES

The Timer2/4/6/8 timer modules have the following features:

- 8-Bit Timer register (TMRx)
- 8-Bit Period register (PRx)
- Readable and Writable (all registers)
- Software Programmable Prescaler (1:1, 1:4, 1:16)
- Software Programmable Postscaler (1:1 to 1:16)
- Interrupt on TMRx Match of PRx
  - **Note:** Throughout this section, generic references are used for register and bit names that are the same, except for an 'x' variable that indicates the item's association with the Timer2, Timer4, Timer6 or Timer8 module. For example, the control register is named TxCON and refers to T2CON, T4CON, T6CON and T8CON.

The Timer2/4/6/8 modules have a control register, shown in Register 16-1. Timer2/4/6/8 can be shut off by clearing control bit, TMRxON (TxCON<2>), to minimize power consumption. The prescaler and postscaler selection of Timer2/4/6/8 also are controlled by this register. Figure 16-1 is a simplified block diagram of the Timer2/4/6/8 modules.

# 16.1 Timer2/4/6/8 Operation

Timer2/4/6/8 can be used as the PWM time base for the PWM mode of the ECCP modules. The TMRx registers are readable and writable, and are cleared on any device Reset. The input clock (FoSC/4) has a prescale option of 1:1, 1:4 or 1:16, selected by control bits, TxCKPS<1:0> (TxCON<1:0>). The match output of TMRx goes through a four-bit postscaler (that gives a 1:1 to 1:16 inclusive scaling) to generate a TMRx interrupt, latched in the flag bit, TMRxIF. Table 16-1 gives each module's flag bit.

Timer Module	Flag Bit
2	PIR1<1>
4	PIR5<0>
6	PIR5<2>
8	PIR5<4>

The interrupt can be enabled or disabled by setting or clearing the Timerx Interrupt Enable bit (TMRxIE), shown in Table 16-2.

#### TABLE 16-2: TIMER2/4/6/8 INTERRUPT ENABLE BITS

Timer Module	Flag Bit
2	PIE1<1>
4	PIE5<0>
6	PIE5<2>
8	PIE5<4>

The prescaler and postscaler counters are cleared when any of the following occurs:

- · A write to the TMRx register
- A write to the TxCON register
- Any device Reset Power-on Reset (POR), MCLR Reset, Watchdog Timer Reset (WDTR) or Brown-out Reset (BOR)

A TMRx is not cleared when a TxCON is written.

Note: The CCP and ECCP modules use Timers, 1 through 8, for some modes. The assignment of a particular timer to a CCP/ECCP module is determined by the Timer to CCP enable bits in the CCPTMRSx registers. For more details, see Register 18-2, Register 18-3 and Register 19-2.

	00 = Prescale										
	01 = Prescale										
	1x = Prescale	er is 16									

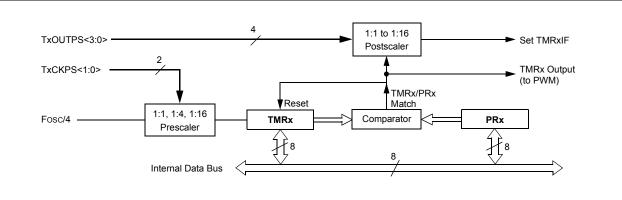

# REGISTER 16-1: TxCON: TIMERx CONTROL REGISTER (TIMER2/4/6/8)

# 16.2 Timer2/4/6/8 Interrupt

The Timer2/4/6/8 modules have 8-bit Period registers, PRx, that are both readable and writable. Timer2/4/6/8 increment from 00h until they match PR2/4/6/8 and then reset to 00h on the next increment cycle. The PRx registers are initialized to FFh upon Reset.

# 16.3 Output of TMRx

The outputs of TMRx (before the postscaler) are used only as a PWM time base for the ECCP modules. They are not used as baud rate clocks for the MSSPx modules as is the Timer2 output.

# 17.0 REAL-TIME CLOCK AND CALENDAR (RTCC)

The key features of the Real-Time Clock and Calendar (RTCC) module are:

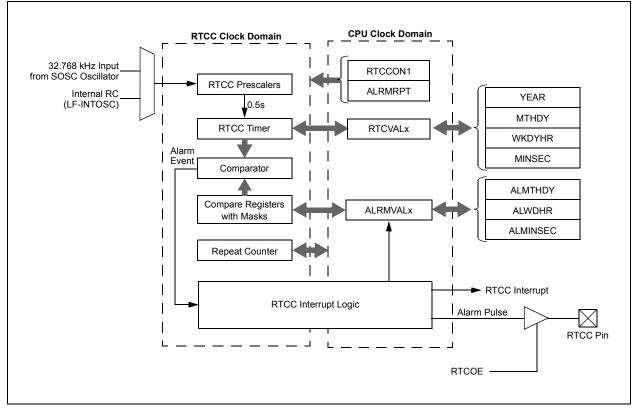

- Hardware Real-Time Clock and Calendar (RTCC)
- Provides hours, minutes and seconds using 24- hour format
- · Visibility of one-half second period
- Provides calendar weekday, date, month and year
- Alarm configurable for half a second, one second, 10 seconds, one minute, 10 minutes, one hour, one day, one week or one month
- · Alarm repeat with decrementing counter
- Alarm with indefinite repeat chime
- · Year 2000 to 2099 leap year correction
- BCD format for smaller software overhead
- · Optimized for long term battery operation
- · Fractional second synchronization

- Multiple clock sources
  - SOSC
  - LPRC
  - 50 Hz
  - 60 Hz
- User calibration of the 32.768 kHz clock crystal frequency with periodic auto-adjust
- Calibration to within ±2.64 seconds error per month
- · Calibrates up to 260 ppm of crystal error

The RTCC module is intended for applications where accurate time must be maintained for an extended period with minimum to no intervention from the CPU. The module is optimized for low-power usage in order to provide extended battery life, while keeping track of time.

The module is a 100-year clock and calendar with automatic leap year detection. The range of the clock is from 00:00:00 (midnight) on January 1, 2000 to 23:59:59 on December 31, 2099.

Hours are measured in 24-hour (military time) format. The clock provides a granularity of one second with half-second visibility to the user.

# FIGURE 17-1: RTCC BLOCK DIAGRAM

# 17.1 RTCC MODULE REGISTERS

The RTCC module registers are divided into the following categories:

# **RTCC Control Registers**

- RTCCON1
- RTCCON2
- RTCCAL
- PADCFG
- ALRMCFG
- ALRMRPT

# **RTCC Value Registers**

- RTCVALH
- RTCVALL
  - Both registers access the following registers:
  - YEAR
  - MONTH
  - DAY
  - WEEKDAY
  - HOUR
  - MINUTE
  - SECOND

# **Alarm Value Registers**

- ALRMVALH
- ALRMVALL Both registers access the following registers:
  - ALRMMNTH
  - ALRMDAY
  - ALRMWD
  - ALRMHR
  - ALRMMIN
  - ALRMSEC
- Note: The RTCVALH and RTCVALL registers can be accessed through RTCRPT<1:0> (RTCCON1<1:0>). ALRMVALH and ALRMVALL can be accessed through ALRMPTR<1:0> (ALRMCFG<1:0>).

bit 3-0 SECONE<3:0>: Binary Coded Decimal Value of Second's Ones Digit bits Contains a value from 0 to 9.

# 17.1.4 RTCEN BIT WRITE

RTCWREN (RTCCON1<5>) must be set before a write to RTCEN can take place. Any write to the RTCEN bit, while RTCWREN = 0, will be ignored.

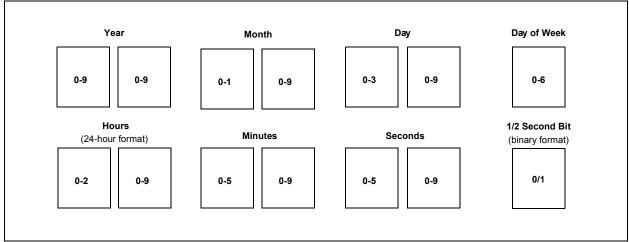

Like the RTCEN bit, the RTCVALH and RTCVALL registers can only be written to when RTCWREN = 1. A write to these registers, while RTCWREN = 0, will be ignored.

# FIGURE 17-2: TIMER DIGIT FORMAT

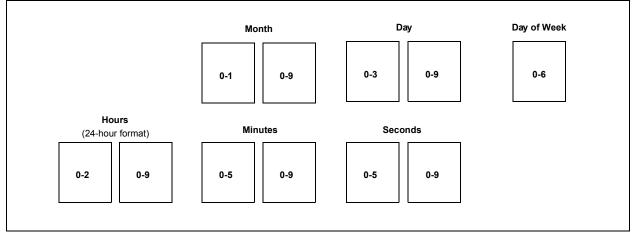

# 17.2 Operation

# 17.2.1 REGISTER INTERFACE

The register interface for the RTCC and alarm values is implemented using the Binary Coded Decimal (BCD) format. This simplifies the firmware when using the module, as each of the digits is contained within its own 4-bit value (see Figure 17-2 and Figure 17-3).

# FIGURE 17-3: ALARM DIGIT FORMAT

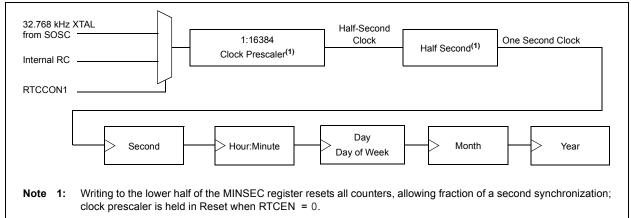

Calibration of the crystal can be done through this module to yield an error of 3 seconds or less per month.

(For further details, see Section 17.2.9 "Calibration".)

# 17.2.2 CLOCK SOURCE

As mentioned earlier, the RTCC module is intended to be clocked by an external Real-Time Clock (RTC) crystal, oscillating at 32.768 kHz, but an internal oscillator can be used. The RTCC clock selection is decided by the RTCOSC bit (CONFIG3L<0>).

#### FIGURE 17-4: CLOCK SOURCE MULTIPLEXING

#### 17.2.2.1 Real-Time Clock Enable

The RTCC module can be clocked by an external, 32.768 kHz crystal (SOSC Oscillator) or the LF-INTOSC Oscillator, which can be selected in CONFIG3L<0>.

If the external clock is used, the SOSC Oscillator should be enabled. If LF-INTOSC is providing the clock, the INTOSC clock can be brought out to the RTCC pin by the RTSECSEL<1:0> bits (RTCCON2<1:0>).

#### 17.2.3 DIGIT CARRY RULES

This section explains which timer values are affected when there is a rollover:

- Time of Day: From 23:59:59 to 00:00:00 with a carry to the Day field
- Month: From 12/31 to 01/01 with a carry to the Year field
- Day of Week: From 6 to 0 with no carry (see Table 17-1)
- Year Carry: From 99 to 00; this also surpasses the use of the RTCC

For the day-to-month rollover schedule, see Table 17-2.

Because the following values are in BCD format, the carry to the upper BCD digit occurs at the count of 10, not 16 (SECONDS, MINUTES, HOURS, WEEKDAY, DAYS and MONTHS).

#### TABLE 17-1: DAY OF WEEK SCHEDULE

31

Note 1: See Section 17.2.4 "Leap Year".

# 17.2.4 LEAP YEAR

Since the year range on the RTCC module is 2000 to 2099, the leap year calculation is determined by any year divisible by four in the above range. Only February is affected in a leap year.

February will have 29 days in a leap year and 28 days in any other year.

#### 17.2.5 GENERAL FUNCTIONALITY

All Timer registers containing a time value of seconds or greater are writable. The user configures the time by writing the required year, month, day, hour, minutes and seconds to the Timer registers, via register pointers. (See Section 17.2.8 "Register Mapping".)

The timer uses the newly written values and proceeds with the count from the required starting point.

The RTCC is enabled by setting the RTCEN bit (RTC-CON1<7>). If enabled, while adjusting these registers, the timer still continues to increment. However, any time the MINSEC register is written to, both of the timer prescalers are reset to '0'. This allows fraction of a second synchronization.

The Timer registers are updated in the same cycle as the WRITE instruction's execution by the CPU. The user must ensure that when RTCEN = 1, the updated registers will not be incremented at the same time. This can be accomplished in several ways:

- By checking the RTCSYNC bit (RTCCON1<4>)
- By checking the preceding digits from which a carry can occur
- By updating the registers immediately following the seconds pulse (or an alarm interrupt)

The user has visibility to the half-second field of the counter. This value is read-only and can be reset only by writing to the lower half of the SECONDS register.

#### 17.2.6 SAFETY WINDOW FOR REGISTER READS AND WRITES

The RTCSYNC bit indicates a time window during which the RTCC clock domain registers can be safely read and written without concern about a rollover. When RTCSYNC = 0, the registers can be safely accessed by the CPU.

Whether RTCSYNC = 1 or 0, the user should employ a firmware solution to ensure that the data read did not fall on a rollover boundary, resulting in an invalid or partial read. This firmware solution would consist of reading each register twice and then comparing the two values. If the two values matched, then a rollover did not occur.

# 17.2.7 WRITE LOCK

In order to perform a write to any of the RTCC Timer registers, the RTCWREN bit (RTCCON1<5>) must be set.

To avoid accidental writes to the RTCC Timer register, it is recommended that the RTCWREN bit (RTCCON1<5>) be kept clear when not writing to the register. For the RTCWREN bit to be set, there is only one instruction cycle time window allowed between the 55h/AA sequence and the setting of RTCWREN. For that reason, it is recommended that users follow the code example in Example 17-1.

#### EXAMPLE 17-1: SETTING THE RTCWREN BIT

movlw	0x55
movwf	EECON2
movlw	0xAA
movwf	EECON2
bsf	RTCCON1, RTCWREN

#### 17.2.8 REGISTER MAPPING

To limit the register interface, the RTCC Timer and Alarm Timer registers are accessed through corresponding register pointers. The RTCC Value register window (RTCVALH and RTCVALL) uses the RTCPTRx bits (RTCCON1<1:0>) to select the required Timer register pair.

By reading or writing to the RTCVALH register, the RTCC Pointer value (RTCPTR<1:0>) decrements by '1' until it reaches '00'. When '00' is reached, the MINUTES and SECONDS value is accessible through RTCVALH and RTCVALL until the pointer value is manually changed.

TABLE 17-3:	<b>RTCVALH AND RTCVALL</b>
	REGISTER MAPPING

RTCPTR<1:0>	RTCC Value Register Window					
RICFIRS1.02	RTCVALH	RTCVALL				
00	MINUTES	SECONDS				
01	WEEKDAY	HOURS				
10	MONTH	DAY				
11	_	YEAR				

The Alarm Value register windows (ALRMVALH and ALRMVALL) use the ALRMPTR bits (ALRMCFG<1:0>) to select the desired Alarm register pair.

By reading or writing to the ALRMVALH register, the Alarm Pointer value, ALRMPTR<1:0>, decrements by '1' until it reaches '00'. When it reaches '00', the ALRMMIN and ALRMSEC values are accessible through ALRMVALH and ALRMVALL until the pointer value is manually changed.

# TABLE 17-4: ALRMVAL REGISTER MAPPING

ALRWPTR-1.02	ALRMVALH	ALRMVALL			
0 0	ALRMMIN	ALRMSEC			
01	ALRMWD	ALRMHR			
10	ALRMMNTH	ALRMDAY			
11	_				

#### 17.2.9 CALIBRATION

The real-time crystal input can be calibrated using the periodic auto-adjust feature. When properly calibrated, the RTCC can provide an error of less than three seconds per month.

To perform this calibration, find the number of error clock pulses and store the value into the lower half of the RTCCAL register. The 8-bit signed value, loaded into RTCCAL, is multiplied by four and will either be added or subtracted from the RTCC timer, once every minute.

To calibrate the RTCC module:

- 1. Use another timer resource on the device to find the error of the 32.768 kHz crystal.
- 2. Convert the number of error clock pulses per minute (see Equation 17-1).

#### EQUATION 17-1: CONVERTING ERROR CLOCK PULSES

(Ideal Frequency (32,758) – Measured Frequency) \* 60 = Error Clocks per Minute

- If the oscillator is *faster* than ideal (negative result from Step 2), the RCFGCALL register value needs to be negative. This causes the specified number of clock pulses to be subtracted from the timer counter once every minute.
- If the oscillator is *slower* than ideal (positive result from Step 2), the RCFGCALL register value needs to be positive. This causes the specified number of clock pulses to be added to the timer counter once every minute.
- 3. Load the RTCCAL register with the correct value.

Writes to the RTCCAL register should occur only when the timer is turned off or immediately after the rising edge of the seconds pulse.

**Note:** In determining the crystal's error value, it is the user's responsibility to include the crystal's initial error from drift due to temperature or crystal aging.

# 17.3 Alarm

The Alarm features and characteristics are:

- · Configurable from half a second to one year
- Enabled using the ALRMEN bit (ALRMCFG<7>, Register 17-4)
- · Offers one-time and repeat alarm options

# 17.3.1 CONFIGURING THE ALARM

The alarm feature is enabled using the ALRMEN bit.

This bit is cleared when an alarm is issued. The bit will not be cleared if the CHIME bit =  $1 \text{ or if ALRMRPT} \neq 0$ .

The interval selection of the alarm is configured through the ALRMCFG bits (AMASK<3:0>); see Figure 17-5. These bits determine which and how many digits of the alarm must match the clock value for the alarm to occur.

The alarm can also be configured to repeat based on a preconfigured interval. The number of times this occurs, after the alarm is enabled, is stored in the ALRMRPT register.

Note:	While the alarm is enabled (ALRMEN = 1), changing any of the registers, other than the RTCCAL, ALRMCFG and ALRMRPT registers and the CHIME bit, can result in a
	false alarm event leading to a false alarm
	interrupt. To avoid this, only change the timer and alarm values while the alarm is
	disabled (ALRMEN = 0). It is recommended that the ALRMCFG and ALRMRPT
	registers and CHIME bit be changed when RTCSYNC = 0.

#### FIGURE 17-5: ALARM MASK SETTINGS

Alarm Mask Setting AMASK<3:0>	Day of the Week	e Month Day	Hours	Minutes Seconds
0000 – Every half second 0001 – Every second				:
0010 – Every 10 seconds				: S
0011 – Every minute				s s s
0100 – Every 10 minutes				m:ss
0101 – Every hour				m m : s s
0110 – Every day			hh	m m : s s
0111 – Every week	d		hh	: m m : s s
1000 – Every month		/ d	d h h	m m : s s
1001 – Every year <sup>(1)</sup>		m m / d	d h h	: m m : s s
Note 1: Annually, except when ca	onfigured fo	r February 29.		

When ALRMCFG = 00 and the CHIME bit = 0 (ALRMCFG<6>), the repeat function is disabled and only a single alarm will occur. The alarm can be repeated up to 255 times by loading the ALRMRPT register with FFh.

After each alarm is issued, the ALRMRPT register is decremented by one. Once the register has reached '00', the alarm will be issued one last time.

After the alarm is issued a last time, the ALRMEN bit is cleared automatically and the alarm turned off. Indefinite repetition of the alarm can occur if the CHIME bit = 1.

When CHIME = 1, the alarm is not disabled when the ALRMRPT register reaches '00', but it rolls over to FF and continues counting indefinitely.

#### 17.3.2 ALARM INTERRUPT

At every alarm event, an interrupt is generated. Additionally, an alarm pulse output is provided that operates at half the frequency of the alarm.

The alarm pulse output is completely synchronous with the RTCC clock and can be used as a trigger clock to other peripherals. This output is available on the RTCC pin. The output pulse is a clock with a 50% duty cycle and a frequency half that of the alarm event (see Figure 17-6).

The RTCC pin can also output the seconds clock. The user can select between the alarm pulse, generated by the RTCC module, or the seconds clock output.

The RTSECSEL<1:0> bits (RTCCON2<1:0>) select between these two outputs:

- Alarm pulse RTSECSEL<1:0> = 00
- Seconds clock RTSECSEL<1:0> = 01

FIGURE 17-6:	TIMER PULSE GENERATION
RTCEN bi	it
ALRMEN bi	t
RTCC Alarm Even	
RTCC Pir	

# 17.4 Sleep Mode

The timer and alarm continue to operate while in Sleep mode. The operation of the alarm is not affected by Sleep, as an alarm event can always wake-up the CPU.

The Idle mode does not affect the operation of the timer or alarm.

# 17.5 Reset

# 17.5.1 DEVICE RESET

When a device Reset occurs, the ALRMRPT register is forced to its Reset state, causing the alarm to be disabled (if enabled prior to the Reset). If the RTCC was enabled, it will continue to operate when a basic device Reset occurs.

# 17.5.2 POWER-ON RESET (POR)

The RTCCON1 and ALRMRPT registers are reset only on a POR. Once the device exits the POR state, the clock registers should be reloaded with the desired values.

The timer prescaler values can be reset only by writing to the SECONDS register. No device Reset can affect the prescalers.

# 17.6 Register Maps

Table 17-5, Table 17-6 and Table 17-7 summarize the registers associated with the RTCC module.

# 18.0 ENHANCED CAPTURE/ COMPARE/PWM (ECCP) MODULE

PIC18FXXJ94 devices have three Enhanced Capture/ Compare/PWM (ECCP) modules: ECCP1, ECCP2 and ECCP3. These modules contain a 16-bit register, which can operate as a 16-bit Capture register, a 16-bit Compare register or a PWM Master/Slave Duty Cycle register. These ECCP modules are upward compatible with CCP

**Note:** Throughout this section, generic references are used for register and bit names that are the same, except for an 'x' variable that indicates the item's association with the CCP1, CCP2 or CCP3 module. For example, the control register is named CCPxCON and refers to CCP1CON, CCP2CON and CCP3CON.

ECCP1, ECCP2 and ECCP3 are implemented as standard CCP modules with enhanced PWM capabilities. These include:

- Provision for two or four output channels
- · Output Steering modes
- · Programmable polarity
- Programmable dead-band control
- Automatic shutdown and restart

The enhanced features are discussed in detail in Section 18.4 "PWM (Enhanced Mode)".

The ECCP1, ECCP2 and ECCP3 modules use the ECCP Control registers, CCP1CON, CCP2CON and CCP3CON. The control registers, CCP4CON through CCP10CON, are for the modules, CCP4 through CCP10.

#### REGISTER 18-2: CCPTMRS0: CCP TIMER SELECT 0 REGISTER

111 = Reserved; do not use

# PIC18F97J94 FAMILY

In addition to the expanded range of modes available through the CCPxCON, the ECCP modules have three additional registers associated with Enhanced PWM operation, Pulse Steering Control and auto-shutdown features. They are:

- ECCPxDEL Enhanced PWM x Control
- PSTRxCON Pulse Steering x Control
- ECCPxAS Auto-Shutdown x Control

# 18.1 ECCP Outputs and Configuration

The Enhanced CCP module may have up to four PWM outputs, depending on the selected operating mode.

These outputs, designated as PxA through PxD, are routed through the PPS-Lite module. Therefore, individual functions can be mapped to any of the remappable I/ O pins (RPn). The outputs that are active depend on the ECCP operating mode selected. The pin assignments are summarized in Table 18-3.

To configure the I/O pins as PWM outputs, the proper PWM mode must be selected by setting the PxM<1:0> and CCPxM<3:0> bits. The appropriate TRIS direction bits for the port pins must also be set as outputs Table 18-3.

### 18.1.1 ECCP MODULE AND TIMER RESOURCES

The ECCP modules use Timers, 1, 2, 3, 4, 6 or 8, depending on the mode selected. These timers are available to CCP modules in Capture, Compare or PWM modes, as shown in Table 18-1.

# TABLE 18-1:ECCP MODE – TIMERRESOURCE

ECCP Mode	Timer Resource
Capture	Timer1 or Timer3
Compare	Timer1 or Timer3
PWM	Timer2, Timer4, Timer6 or Timer8

The assignment of a particular timer to a module is determined by the timer to ECCP enable bits in the CCPTMRS0 register (Register 18-2). The interactions between the two modules are depicted in Figure 18-1. Capture operations are designed to be used when the timer is configured for Synchronous Counter mode. Capture operations may not work as expected if the associated timer is configured for Asynchronous Counter mode.

# 18.2 Capture Mode

In Capture mode, the CCPRxH:CCPRxL register pair captures the 16-bit value of the TMR1 or TMR3 registers when an event occurs on the corresponding ECCPx pin. An event is defined as one of the following:

- · Every falling edge
- · Every rising edge
- Every fourth rising edge
- Every 16<sup>th</sup> rising edge

The event is selected by the mode select bits, CCPxM<3:0> (CCPxCON<3:0>). When a capture is made, the interrupt request flag bit, CCPxIF, is set (see Table 18-2). The flag must be cleared by software. If another capture occurs before the value in the CCPRxH/L register is read, the old captured value is overwritten by the new captured value.

#### TABLE 18-2: ECCP1/2/3 INTERRUPT FLAG BITS

ECCP Module	Flag Bit
1	PIR3<1>
2	PIR3<2>
3	PIR4<0>

#### 18.2.1 ECCP PIN CONFIGURATION

In Capture mode, the appropriate ECCPx pin should be configured as an input by setting the corresponding TRIS direction bit.

Note:	If the ECCPx pin is configured as an out-
	put, a write to the port can cause a capture
	condition.

# 18.2.2 TIMER1/2/3/4/5/6/8 MODE SELECTION

The timers that are to be used with the capture feature (Timer1/2/3/4/5/6 or 8) must be running in Timer mode or Synchronized Counter mode. In Asynchronous Counter mode, the capture operation will not work. The timer to be used with each ECCP module is selected in the CCPTMRS0 register (Register 18-2).

# 18.2.3 SOFTWARE INTERRUPT

When the Capture mode is changed, a false capture interrupt may be generated. The user should keep the CCPxIE interrupt enable bit clear to avoid false interrupts. The interrupt flag bit, CCPxIF, should also be cleared following any such change in operating mode.

# 18.2.4 ECCP PRESCALER

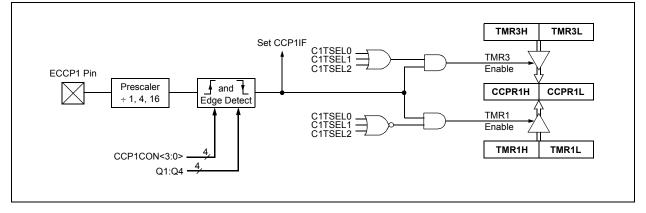

There are four prescaler settings in Capture mode; they are specified as part of the operating mode selected by the mode select bits (CCPxM<3:0>). Whenever the ECCP module is turned off, or Capture mode is disabled, the prescaler counter is cleared. This means that any Reset will clear the prescaler counter.

Switching from one capture prescaler to another may generate an interrupt. Also, the prescaler counter will not be cleared; therefore, the first capture may be from a non-zero prescaler. Example 18-1 provides the recommended method for switching between capture prescalers. This example also clears the prescaler counter and will not generate the "false" interrupt.

#### EXAMPLE 18-1: CHANGING BETWEEN CAPTURE PRESCALERS

		;	new prescaler mode
		;	value and ECCP ON
MOVWF	CCP1CON	;	Load CCP1CON with
		;	this value

# FIGURE 18-1: CAPTURE MODE OPERATION BLOCK DIAGRAM

# 18.3 Compare Mode

In Compare mode, the 16-bit CCPRx register value is constantly compared against the Timer register pair value selected in the CCPTMR0 register. When a match occurs, the ECCPx pin can be:

- Driven high
- Driven low
- Toggled (high-to-low or low-to-high)
- Unchanged (that is, reflecting the state of the I/O latch)

The action on the pin is based on the value of the mode select bits (CCPxM<3:0>). At the same time, the interrupt flag bit, CCPxIF, is set.

# 18.3.1 ECCPx PIN CONFIGURATION

Users must configure the ECCPx pin as an output by clearing the appropriate TRIS bit.

Note:	Clearing the CCPxCON register will force
	the ECCPx compare output latch (depend-
	ing on device configuration) to the default
	low level. This is not the PORTx I/O data
	latch.

### 18.3.2 TIMER1/2/3/4/5/6/8 MODE SELECTION

Timer1/2/3/4, 6 or 8, must be running in Timer mode or Synchronized Counter mode if the ECCP module is using the compare feature. In Asynchronous Counter mode, the compare operation will not work reliably.

# 18.3.3 SOFTWARE INTERRUPT MODE

When the Generate Software Interrupt mode is chosen (CCPxM<3:0> = 1010), the ECCPx pin is not affected; only the CCPxIF interrupt flag is affected.

# 18.3.4 SPECIAL EVENT TRIGGER

The ECCP module is equipped with a Special Event Trigger. This is an internal hardware signal generated in Compare mode to trigger actions by other modules. The Special Event Trigger is enabled by selecting the Compare Special Event Trigger mode (CCPxM<3:0> = 1011).

The Special Event Trigger resets the Timer register pair for whichever timer resource is currently assigned as the module's time base. This allows the CCPRx registers to serve as a programmable period register for either timer.

The Special Event Trigger can also start an A/D conversion. In order to do this, the A/D Converter must already be enabled.

#### TMR1H TMR1L n TMR3H TMR3L Special Event Trigger C1TSEL0 (Timer1/Timer3 Reset, A/D Trigger) C1TSEL1-C1TSEL2 Set CCP1IF ECCP1 Pin S Q Output Compare Comparator Logic Match R TRIS 4 Output Enable CCPR1H CCPR1L CCP1CON<3:0>

# FIGURE 18-2: COMPARE MODE OPERATION BLOCK DIAGRAM

# 18.4 PWM (Enhanced Mode)

The Enhanced PWM mode can generate a PWM signal on up to four different output pins, with up to 10 bits of resolution. It can do this through four different PWM Output modes:

- Single PWM
- · Half-Bridge PWM
- Full-Bridge PWM, Forward mode
- · Full-Bridge PWM, Reverse mode

To select an Enhanced PWM mode, the PxM bits of the CCPxCON register must be set appropriately.

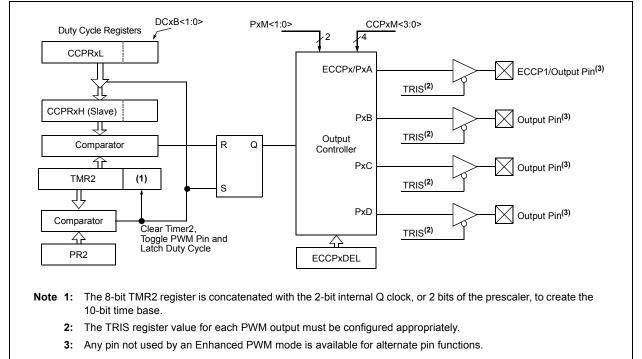

The PWM outputs are multiplexed with I/O pins and are designated: PxA, PxB, PxC and PxD. The polarity of the PWM pins is configurable and is selected by setting the CCPxM bits in the CCPxCON register appropriately.

Table 18-1provides the pin assignments for eachEnhanced PWM mode.

Figure 18-3 provides an example of a simplified block diagram of the Enhanced PWM module.

**Note:** To prevent the generation of an incomplete waveform when the PWM is first enabled, the ECCP module waits until the start of a new PWM period before generating a PWM signal.

#### FIGURE 18-3: EXAMPLE SIMPLIFIED BLOCK DIAGRAM OF THE ENHANCED PWM MODE

ECCP Mode	PxM<1:0>	PxA	PxB	PxC	PxD

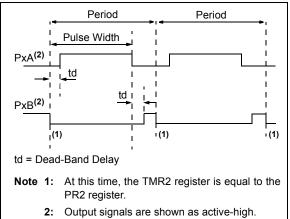

# FIGURE 18-5: EXAMPLE ENHANCED PWM OUTPUT RELATIONSHIPS (ACTIVE-LOW STATE)

# 18.4.1 HALF-BRIDGE MODE

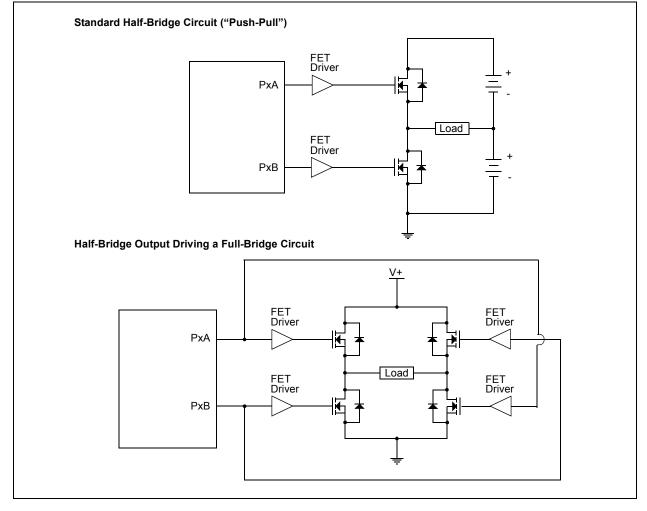

In Half-Bridge mode, two pins are used as outputs to drive push-pull loads. The PWM output signal is output on the PxA pin, while the complementary PWM output signal is output on the PxB pin (see Figure 18-6). This mode can be used for half-bridge applications, as shown in Figure 18-7, or for full-bridge applications, where four power switches are being modulated with two PWM signals.

In Half-Bridge mode, the programmable dead-band delay can be used to prevent shoot-through current in halfbridge power devices. The value of the PxDC<6:0> bits of the ECCPxDEL register sets the number of instruction cycles before the output is driven active. If the value is greater than the duty cycle, the corresponding output remains inactive during the entire cycle. For more details on the dead-band delay operations, see Section 18.4.6 "Programmable Dead-Band Delay Mode". Since the PxA and PxB outputs are multiplexed with the PORT data latches, the associated TRIS bits must be cleared to configure PxA and PxB as outputs.

# FIGURE 18-7: EXAMPLE OF HALF-BRIDGE APPLICATIONS

In the Reverse mode, the PxC pin is driven to its active state and the PxB pin is modulated, while the PxA and

PxD pins are driven to their inactive state, as provided in

The PxA, PxB, PxC and PxD outputs are multiplexed

with the port data latches. The associated TRIS bits

must be cleared to configure the PxA, PxB, PxC and

# 18.4.2 FULL-BRIDGE MODE

In Full-Bridge mode, all four pins are used as outputs. An example of a full-bridge application is provided in Figure 18-8.

In the Forward mode, the PxA pin is driven to its active state and the PxD pin is modulated, while the PxB and PxC pins are driven to their inactive state, as provided in Figure 18-9.

FIGURE 18-8: EXAMPLE OF FULL-BRIDGE APPLICATION

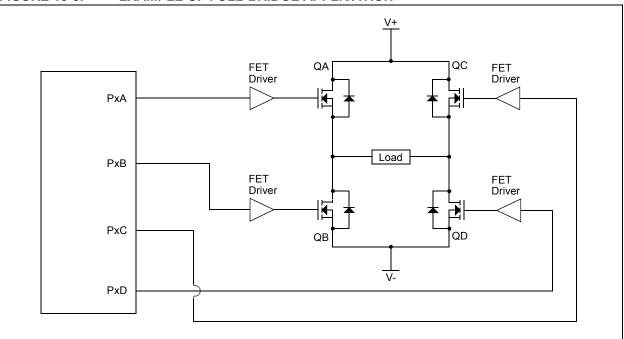

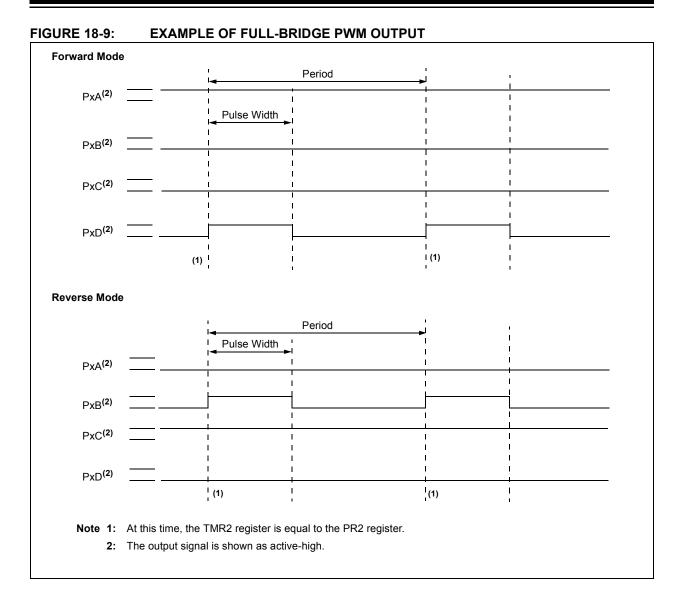

Figure 18-9.

PxD pins as outputs.

#### 18.4.2.1 Direction Change in Full-Bridge Mode

In Full-Bridge mode, the PxM1 bit in the CCPxCON register allows users to control the forward/reverse direction. When the application firmware changes this direction control bit, the module will change to the new direction on the next PWM cycle.

A direction change is initiated in software by changing the PxM1 bit of the CCPxCON register. The following sequence occurs prior to the end of the current PWM period:

- The modulated outputs (PxB and PxD) are placed in their inactive state.
- The associated unmodulated outputs (PxA and PxC) are switched to drive in the opposite direction.
- PWM modulation resumes at the beginning of the next period.

For an illustration of this sequence, see Figure 18-10.

The Full-Bridge mode does not provide a dead-band delay. As one output is modulated at a time, a deadband delay is generally not required. There is a situation where a dead-band delay is required. This situation occurs when both of the following conditions are true:

- The direction of the PWM output changes when the duty cycle of the output is at or near 100%.
- The turn-off time of the power switch, including the power device and driver circuit, is greater than the turn-on time.

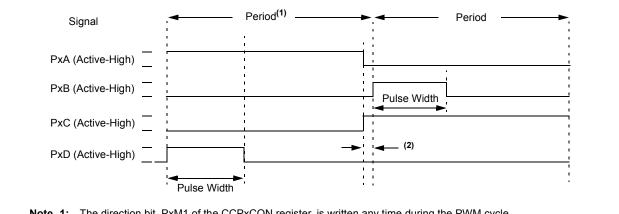

Figure 18-11 shows an example of the PWM direction changing from forward to reverse, at a near 100% duty cycle. In this example, at time, t1, the PxA and PxD outputs become inactive, while the PxC output becomes active. Since the turn-off time of the power devices is longer than the turn-on time, a shoot-through current will flow through power devices, QC and QD (see Figure 18-8), for the duration of 't'. The same phenomenon will occur to power devices, QA and QB, for PWM direction change from reverse to forward.

If changing PWM direction at high duty cycle is required for an application, two possible solutions for eliminating the shoot-through current are:

- Reduce PWM duty cycle for one PWM period before changing directions.
- Use switch drivers that can drive the switches off faster than they can drive them on.

Other options to prevent shoot-through current may exist.

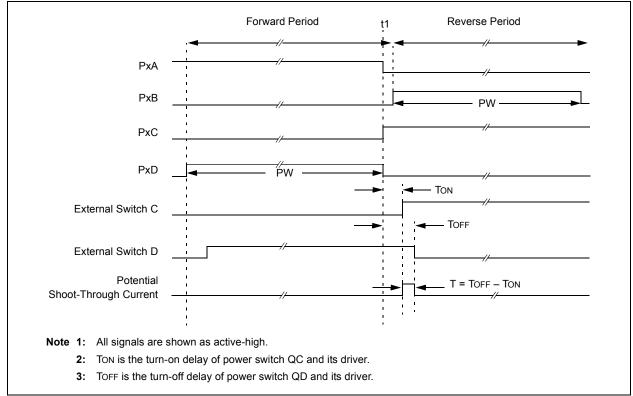

# FIGURE 18-10: EXAMPLE OF PWM DIRECTION CHANGE

Note 1: The direction bit, PxM1 of the CCPxCON register, is written any time during the PWM cycle.

2: When changing directions, the PxA and PxC signals switch before the end of the current PWM cycle. The modulated PxB and PxD signals are inactive at this time. The length of this time is: (1/Fosc) • TMR2 Prescale Value.

# FIGURE 18-11: EXAMPLE OF PWM DIRECTION CHANGE AT NEAR 100% DUTY CYCLE

# 18.4.3 START-UP CONSIDERATIONS

When any PWM mode is used, the application hardware must use the proper external pull-up and/or pull-down resistors on the PWM output pins.

Note:	When the microcontroller is released from
	Reset, all of the I/O pins are in the high-
	impedance state. The external circuits
	must keep the power switch devices in the
	OFF state until the microcontroller drives
	the I/O pins with the proper signal levels or
	activates the PWM output(s).

The CCPxM<1:0> bits of the CCPxCON register allow the user to choose whether the PWM output signals are active-high or active-low for each pair of PWM output pins (PxA/PxC and PxB/PxD). The PWM output polarities must be selected before the PWM pin output drivers are enabled. Changing the polarity configuration while the PWM pin output drivers are enabled is not recommended since it may result in damage to the application circuits.

The PxA, PxB, PxC and PxD output latches may not be in the proper states when the PWM module is initialized. Enabling the PWM pin output drivers, at the same time as the Enhanced PWM modes, may cause damage to the application circuit. The Enhanced PWM modes must be enabled in the proper Output mode and complete a full PWM cycle before enabling the PWM pin output drivers. The completion of a full PWM cycle is indicated by the TMR2IF or TMR4IF bit of the PIR1 or PIR5 register being set as the second PWM period begins.

# 18.4.4 ENHANCED PWM AUTO-SHUTDOWN MODE

The PWM mode supports an Auto-Shutdown mode that will disable the PWM outputs when an external shutdown event occurs. Auto-Shutdown mode places the PWM output pins into a predetermined state. This mode is used to help prevent the PWM from damaging the application.

The auto-shutdown sources are selected using the ECCPxAS<2:0> bits (ECCPxAS<6:4>). A shutdown event may be generated by:

- A logic '0' on the pin that is assigned the FLT0 input function
- Comparator C1
- Comparator C2
- · Setting the ECCPxASE bit in firmware

A shutdown condition is indicated by the ECCPxASE (Auto-Shutdown Event Status) bit (ECCPxAS<7>). If the bit is a '0', the PWM pins are operating normally. If the bit is a '1', the PWM outputs are in the shutdown state.

When a shutdown event occurs, two things happen:

- The ECCPxASE bit is set to '1'. The ECCPxASE will remain set until cleared in firmware or an auto-restart occurs. (See Section 18.4.5 "Auto-Restart Mode".)
- The enabled PWM pins are asynchronously placed in their shutdown states. The PWM output pins are grouped into pairs (PxA/PxC and PxB/ PxD). The state of each pin pair is determined by the PSSxAC and PSSxBD bits (ECCPxAS<3:2> and <1:0>, respectively).

Each pin pair may be placed into one of three states:

- Drive logic '1'
- Drive logic '0'
- Tri-state (high-impedance)

Note 1:	The auto-shutdown condition is a level-based signal, not an edge-based signal. As long as the l present, the auto-shutdown will persist.

- 2: Writing to the ECCPxASE bit is disabled while an auto-shutdown condition persists.
- **3:** Once the auto-shutdown condition has been removed and the PWM restarted (either through firmware or auto-restart), the PWM signal will always restart at the beginning of the next PWM period.

level is

# FIGURE 18-12: PWM AUTO-SHUTDOWN WITH FIRMWARE RESTART (PxRSEN = 0)

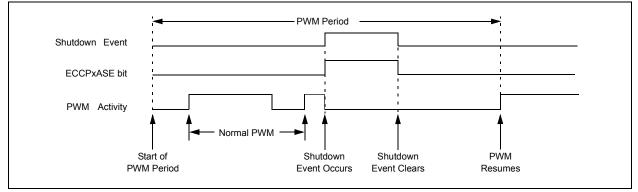

# 18.4.5 AUTO-RESTART MODE

The Enhanced PWM can be configured to automatically restart the PWM signal once the auto-shutdown condition has been removed. Auto-restart is enabled by setting the PxRSEN bit (ECCPxDEL<7>).

If auto-restart is enabled, the ECCPxASE bit will remain set as long as the auto-shutdown condition is active. When the auto-shutdown condition is removed, the ECCPxASE bit will be cleared via hardware and normal operation will resume. The module will wait until the next PWM period begins, however, before re-enabling the output pin. This behavior allows the auto-shutdown with auto-restart features to be used in applications based on current mode of PWM control.

# FIGURE 18-13: PWM AUTO-SHUTDOWN WITH AUTO-RESTART ENABLED (PxRSEN = 1)

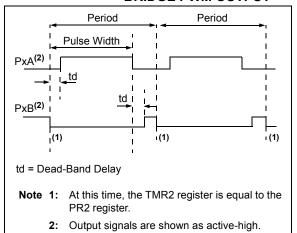

#### 18.4.6 PROGRAMMABLE DEAD-BAND DELAY MODE

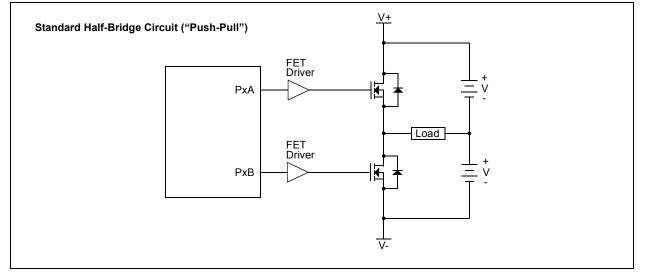

In half-bridge applications, where all power switches are modulated at the PWM frequency, the power switches normally require more time to turn off than to turn on. If both the upper and lower power switches are switched at the same time (one turned on and the other turned off), both switches may be on for a short period until one switch completely turns off. During this brief interval, a very high current (shoot-through current) will flow through both power switches, shorting the bridge supply. To avoid this potentially destructive shoot-through current from flowing during switching, turning on either of the power switches is normally delayed to allow the other switch to completely turn off.

In Half-Bridge mode, a digitally programmable deadband delay is available to avoid shoot-through current from destroying the bridge power switches. The delay occurs at the signal transition from the non-active state to the active state. For an illustration, see Figure 18-14. The lower seven bits of the associated ECCPxDEL register (Register 18-4) set the delay period in terms of microcontroller instruction cycles (TcY or 4 Tosc).

# 18.4.7 PULSE STEERING MODE

In Single Output mode, pulse steering allows any of the PWM pins to be the modulated signal. Additionally, the same PWM signal can simultaneously be available on multiple pins.

Once the Single Output mode is selected (CCPxM<3:2> = 11 and PxM<1:0> = 00 of the CCPxCON register), the user firmware can bring out the same PWM signal to one, two, three or four output pins by setting the appropriate STR<D:A> bits (PSTRxCON<3:0>), as provided in Table 18-3.

Note: The associated TRIS bits must be set to output ('0') to enable the pin output driver in order to see the PWM signal on the pin.

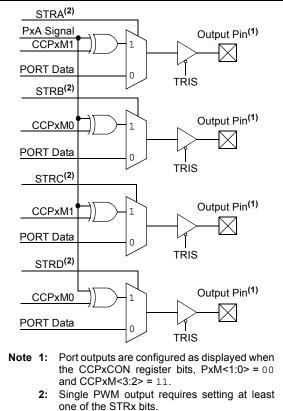

While the PWM Steering mode is active, the CCPxM<1:0> bits (CCPxCON<1:0>) select the PWM output polarity for the Px<D:A> pins.

The PWM auto-shutdown operation also applies to the PWM Steering mode, as described in **Section 18.4.4** "Enhanced PWM Auto-shutdown mode". An auto-shutdown event will only affect pins that have PWM outputs enabled.

#### FIGURE 18-16: SIMPLIFIED STEERING BLOCK DIAGRAM

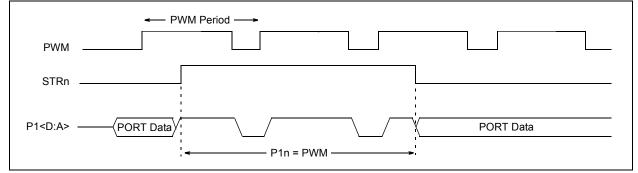

# 18.4.7.1 Steering Synchronization

The STRSYNC bit of the PSTRxCON register gives the user two choices for when the steering event will happen. When the STRSYNC bit is '0', the steering event will happen at the end of the instruction that writes to the PSTRxCON register. In this case, the output signal at the Px<D:A> pins may be an incomplete PWM waveform. This operation is useful when the user firmware needs to immediately remove a PWM signal from the pin.

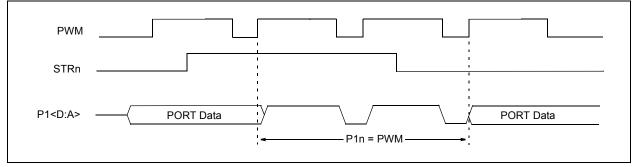

When the STRSYNC bit is '1', the effective steering update will happen at the beginning of the next PWM period. In this case, steering on/off the PWM output will always produce a complete PWM waveform.

Figures 18-17 and 18-18 illustrate the timing diagrams of the PWM steering depending on the STRSYNC setting.

# FIGURE 18-17: EXAMPLE OF STEERING EVENT AT END OF INSTRUCTION (STRSYNC = 0)

#### FIGURE 18-18: EXAMPLE OF STEERING EVENT AT BEGINNING OF INSTRUCTION (STRSYNC = 1)

# 18.4.8 OPERATION IN POWER-MANAGED MODES

In Sleep mode, all clock sources are disabled. Timer2/ 4/6/8 will not increment and the state of the module will not change. If the ECCPx pin is driving a value, it will continue to drive that value. When the device wakes up, it will continue from this state. If Two-Speed Startups are enabled, the initial start-up frequency from HF-INTOSC and the postscaler may not be stable immediately.

In PRI\_IDLE mode, the primary clock will continue to clock the ECCPx module without change.

# 18.4.8.1 Operation with Fail-Safe Clock Monitor (FSCM)

If the Fail-Safe Clock Monitor (FSCM) is enabled, a clock failure will force the device into the power-managed RC\_RUN mode and the OSCFIF bit of the PIR2 register will be set. The ECCPx will then be clocked from the internal oscillator clock source, which may have a different clock frequency than the primary clock.

# 18.4.9 EFFECTS OF A RESET

Both Power-on Reset and subsequent Resets will force all ports to Input mode and the ECCP registers to their Reset states.

This forces the ECCP module to reset to a state compatible with previous, non-enhanced CCP modules used on other PIC18 and PIC16 devices.

# 19.0 CAPTURE/COMPARE/PWM (CCP) MODULES

PIC18FXXJ94 devices have seven CCP (Capture/ Compare/PWM) modules, designated CCP4 through CCP10. All the modules implement standard Capture, Compare and Pulse-Width Modulation (PWM) modes.

Note: Throughout this section, generic references are used for register and bit names that are the same, except for an 'x' variable that indicates the item's association with the specific CCP module. For example, the control register is named CCPxCON and refers to CCP4CON through CCP10CON. Each CCP module contains a 16-bit register that can operate as a 16-bit Capture register, a 16-bit Compare register or a PWM Master/Slave Duty Cycle register. For the sake of clarity, all CCP module operation in the following sections is described with respect to CCP4, but is equally applicable to CCP5 through CCP10.

# **19.1 CCP Module Configuration**

Each Capture/Compare/PWM module is associated with a control register (generically, CCPxCON) and a data register (CCPRx). The data register, in turn, is comprised of two 8-bit registers: CCPRxL (low byte) and CCPRxH (high byte). All registers are both readable and writable.

#### 19.1.1 CCP MODULES AND TIMER RESOURCES

The CCP modules utilize Timers, 1 through 8, that vary with the selected mode. Various timers are available to the CCP modules in Capture, Compare or PWM modes, as shown in Table 19-1.

#### TABLE 19-1: CCP MODE – TIMER RESOURCE

CCP Mode	Timer Resource			
Capture	Timer1 Timer2 or Timer 5			
Compare	Timer1, Timer3 or Timer 5			
PWM	Timer2, Timer4, Timer 6 or Timer8			

The assignment of a particular timer to a module is determined by the timer to CCP enable bits in the CCPTMRSx registers. (See Register 19-2 and Register 19-3.) All of the modules may be active at once and may share the same timer resource if they are configured to operate in the same mode (Capture/ Compare or PWM) at the same time.

The CCPTMRS1 register selects the timers for CCP modules, 7, 6, 5 and 4, and the CCPTMRS2 register selects the timers for CCP modules, 10, 9 and 8. The possible configurations are shown in Table 19-2 and Table 19-3.

TABLE 19-2:	TIMER ASSIGNMENTS FOR CCP MODULES 4, 5, 6 AND 7

1 1	Reserv	ed <sup>(1)</sup>	11	Reserv	red <sup>(1)</sup>						

Note 1: Do not use the reserved bits.

# 19.1.2 OPEN-DRAIN OUTPUT OPTION

When operating in Output mode (the Compare or PWM modes), the drivers for the CCPx pins can be optionally configured as open-drain outputs. This feature allows the voltage level on the pin to be pulled to a higher level through an external pull-up resistor and allows the output to communicate with external circuits without the need for additional level shifters.

The open-drain output option is controlled by the CCPxOD bits (ODCON2<7:1>). Setting the appropriate bit configures the pin for the corresponding module for open-drain operation.

# 19.2 Capture Mode

In Capture mode, the CCPR4H:CCPR4L register pair captures the 16-bit value of the Timer register selected in the CCPTMRS1 when an event occurs on the CCP4 pin. An event is defined as one of the following:

- Every falling edge
- Every rising edge
- Every 4th rising edge
- Every 16th rising edge

The event is selected by the mode select bits, CCP4M<3:0> (CCP4CON<3:0>). When a capture is made, the interrupt request flag bit, CCP4IF (PIR4<1>), is set. (It must be cleared in software.) If another capture occurs before the value in CCPR4 is read, the old captured value is overwritten by the new captured value.

Figure 19-1 shows the Capture mode block diagram.

#### 19.2.1 CCP PIN CONFIGURATION

In Capture mode, the appropriate CCPx pin should be configured as an input by setting the corresponding TRIS direction bit.

**Note:** If the CCPx pin is configured as an output, a write to the port can cause a capture condition.

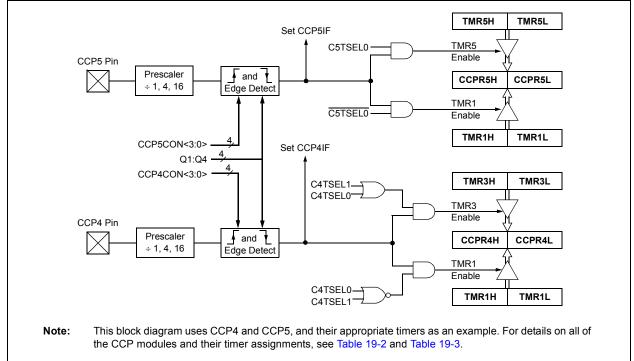

# 19.2.2 TIMER1/3/5/7 MODE SELECTION

For the available timers (1/3/5) to be used for the capture feature, the used timers must be running in Timer mode or Synchronized Counter mode. In Asynchronous Counter mode, the capture operation will not work.

The timer to be used with each CCP module is selected in the CCPTMRSx registers. (See Section 19.1.1 "CCP Modules and Timer Resources".)

Details of the timer assignments for the CCP modules are given in Table 19-2 and Table 19-3.

#### 19.2.3 SOFTWARE INTERRUPT

When the Capture mode is changed, a false capture interrupt may be generated. The user should keep the CCP4IE bit (PIE4<1>) clear to avoid false interrupts and should clear the flag bit, CCP4IF, following any such change in operating mode.

#### 19.2.4 CCP PRESCALER

There are four prescaler settings in Capture mode. They are specified as part of the operating mode selected by the mode select bits (CCP4M<3:0>). Whenever the CCP module is turned off, or the CCP module is not in Capture mode, the prescaler counter is cleared. This means that any Reset will clear the prescaler counter. Switching from one capture prescaler to another may generate an interrupt. Doing that will also not clear the prescaler counter – meaning the first capture may be from a non-zero prescaler.

Example 19-1 shows the recommended method for switching between capture prescalers. This example also clears the prescaler counter and will not generate the "false" interrupt.

EXAMPLE 19-1:	CHANGING BETWEEN
	CAPTURE PRESCALERS

	_CAPT_PS ;	Turn CCP module off Load WREG with the
	;	new prescaler mode
	;	value and CCP ON
MOVWF CCP4	łCON ;	Load CCP4CON with
	;	this value

# 19.3 Compare Mode

In Compare mode, the 16-bit CCPR4 register value is constantly compared against the Timer register pair value selected in the CCPTMR1 register. When a match occurs, the CCP4 pin can be:

- Driven high
- Driven low
- Toggled (high-to-low or low-to-high)
- Unchanged (that is, reflecting the state of the I/O latch)

The action on the pin is based on the value of the mode select bits (CCP4M<3:0>). At the same time, the interrupt flag bit, CCP4IF, is set.

Figure 19-2 gives the Compare mode block diagram

#### 19.3.1 CCP PIN CONFIGURATION

The user must configure the CCPx pin as an output by clearing the appropriate TRIS bit.

Note:	Clearing the CCPxCON register will force
	the CCPx compare output latch (depend-
	ing on device configuration) to the default
	low level. This is not the PORTx I/O data
	latch.

# 19.3.2 TIMER1/3/5 MODE SELECTION

If the CCP module is using the compare feature in conjunction with any of the Timer1/3/5 timers, the timers must be running in Timer mode or Synchronized Counter mode. In Asynchronous Counter mode, the compare operation will not work.

**Note:** Details of the timer assignments for the CCP modules are given in Table 19-2 and Table 19-3.

#### 19.3.3 SOFTWARE INTERRUPT MODE

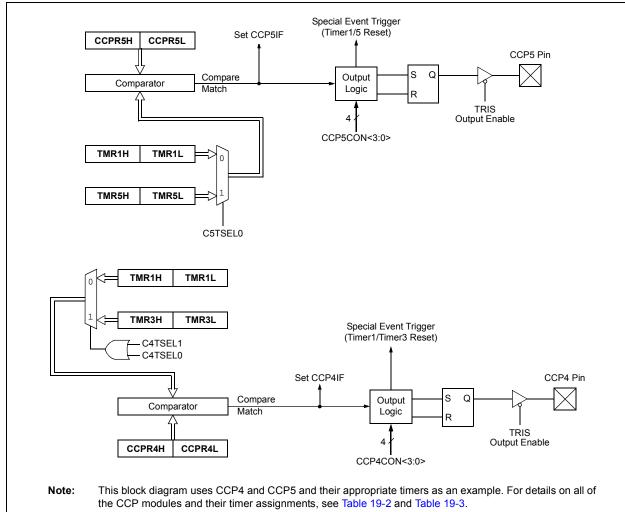

When the Generate Software Interrupt mode is chosen (CCP4M<3:0> = 1010), the CCP4 pin is not affected. Only a CCP interrupt is generated, if enabled, and the CCP4IE bit is set.

#### 19.3.4 SPECIAL EVENT TRIGGER

Both CCP modules are equipped with a Special Event Trigger. This is an internal hardware signal, generated in Compare mode, to trigger actions by other modules. The Special Event Trigger is enabled by selecting the Compare Special Event Trigger mode (CCP4M<3:0> = 1011).

For either CCP module, the Special Event Trigger resets the Timer register pair for whichever timer resource is currently assigned as the module's time base. This allows the CCPRx registers to serve as a Programmable Period register for either timer.

The Special Event Trigger for CCP4 cannot start an A/  $\ensuremath{\mathsf{D}}$  conversion.

#### FIGURE 19-2: COMPARE MODE OPERATION BLOCK DIAGRAM

# 19.4 PWM Mode

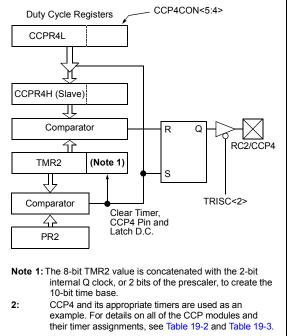

In Pulse-Width Modulation (PWM) mode, the CCP4 pin produces up to a 10-bit resolution PWM output. Since the CCP4 pin is multiplexed with a PORTC or PORTE data latch, the appropriate TRIS bit must be cleared to make the CCP4 pin an output.

Note:	Clearing the CCPxCON register will force
	the CCPx compare output latch (depend-
	ing on device configuration) to the default
	low level. This is not the PORTx I/O data
	latch.

Figure 19-3 shows a simplified block diagram of the CCP4 module in PWM mode.

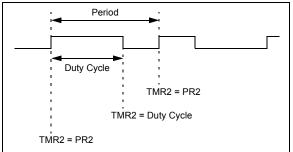

For a step-by-step procedure on how to set up the CCP module for PWM operation, see Section 19.4.3 "Setup for PWM Operation".

A PWM output (Figure 19-4) has a time base (period) and a time that the output stays high (duty cycle). The frequency of the PWM is the inverse of the period (1/ period).

#### FIGURE 19-4: PWM OUTPUT

#### 19.4.1 PWM PERIOD

The PWM period is specified by writing to the PR2 register. The PWM period can be calculated using the following formula:

#### EQUATION 19-1: PWM PERIOD CALCULATION

PWM Period	=[(PR2) + 1] • 4 • Tosc •
	(TMR2 Prescale Value)

PWM frequency is defined as 1/[PWM period].

When TMR2 is equal to PR2, the following three events occur on the next increment cycle:

- TMR2 is cleared
- The CCP4 pin is set
  - (An exception: If PWM Duty Cycle = 0%, the CCP4 pin will not be set)
- The PWM duty cycle is latched from CCPR4L into CCPR4H

Note:	The Timer2 postscalers	(see
	Section 16.0 "Timer2/4/6/8 Mc	odules")
	are not used in the determination	n of the
	PWM frequency. The postscaler	could be
	used to have a servo update rate	at a dif-
	ferent frequency than the PWM o	utput.

# 19.4.2 PWM DUTY CYCLE

The PWM duty cycle is specified, to use CCP4 as an example, by writing to the CCPR4L register and to the CCP4CON<5:4> bits. Up to 10-bit resolution is available. The CCPR4L contains the eight MSbs and the CCP4CON<5:4> contains the two LSbs. This 10-bit value is represented by CCPR4L:CCP4CON<5:4>. The following equation is used to calculate the PWM duty cycle in time:

# EQUATION 19-2: PWM DUTY CYCLE (IN TIME)

PWM Duty Cycle = (CCPR4L:CCP4CON<5:4>) • Tosc • (TMR2 Prescale Value)

CCPR4L and CCP4CON<5:4> can be written to at any time, but the duty cycle value is not latched into CCPR4H until after a match between PR2 and TMR2 occurs (that is, the period is complete). In PWM mode, CCPR4H is a read-only register.

The CCPR4H register and a two-bit internal latch are used to double-buffer the PWM duty cycle. This double-buffering is essential for glitchless PWM operation.

When the CCPR4H and two-bit latch match TMR2, concatenated with an internal two-bit Q clock or two bits of the TMR2 prescaler, the CCP4 pin is cleared.

The maximum PWM resolution (bits) for a given PWM frequency is given by the equation:

#### EQUATION 19-3: PWM RESOLUTION

PWM Resolution (max) = 
$$\frac{\log(\frac{FOSC}{FPWM})}{\log(2)}$$
 bits

Note: If the PWM duty cycle value is longer than the PWM period, the CCP4 pin will not be cleared.

IABLE 19-4: EXAMPLE PWM FREQUENCIES AND RESOLUTIONS AT 40 MHZ	TABLE 19-4:	<b>EXAMPLE PWM FREQUENCIES AND RESOLUTIONS AT 40 MHz</b>
---	-------------	--

PWM Frequency	2.44 kHz	9.77 kHz	39.06 kHz	156.25 kHz	312.50 kHz	416.67 kHz
Timer Prescaler (1, 4, 16)	16	4	1	1	1	1
PR2 Value	FFh	FFh	FFh	3Fh	1Fh	17h
Maximum Resolution (bits)	10	10	10	8	7	6.58

# 19.4.3 SETUP FOR PWM OPERATION

To configure the CCP module for PWM operation using CCP4 as an example:

- 1. Set the PWM period by writing to the PR2 register.
- 2. Set the PWM duty cycle by writing to the CCPR4L register and CCP4CON<5:4> bits.
- 3. Make the CCP4 pin an output by clearing the appropriate TRIS bit.
- 4. Set the TMR2 prescale value, then enable Timer2 by writing to T2CON.
- 5. Configure the CCP4 module for PWM operation.

# 20.0 MASTER SYNCHRONOUS SERIAL PORT (MSSP) MODULE

# 20.1 Master SSP (MSSP) Module Overview

The Master Synchronous Serial Port (MSSP) module is a serial interface, useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D Converters, etc. The MSSP module can operate in one of two modes:

- Serial Peripheral Interface (SPI)
- Inter-Integrated Circuit<sup>™</sup> (I<sup>2</sup>C)
  - Full Master mode
  - Slave mode (with general address call)

The I<sup>2</sup>C interface supports the following modes in hardware:

- Master mode
- Multi-Master mode
- Slave mode with 5-bit and 7-bit address masking (with address masking for both 10-bit and 7-bit addressing)

All members of the PIC18FXXJ94 have two MSSP modules, designated as MSSP1 and MSSP2. Each module operates independently of the other.

Note: Throughout this section, generic references to an MSSP module in any of its operating modes may be interpreted as being equally applicable to MSSP1 or MSSP2. Register names and module I/O signals use the generic designator 'x' to indicate the use of a numeral to distinguish a particular module when required. Control bit names are not individuated.

# 20.2 Control Registers

Each MSSP module has four associated control registers. These include a STATUS register (SSPxSTAT) and three control registers (SSPxCON1, SSPxCON2, and SSPxCON3). The use of these registers and their individual Configuration bits differ significantly depending on whether the MSSP module is operated in SPI or  $I^2C$  mode.

Additional details are provided under the individual sections. On all PIC18F97J94 family devices, the SPI DMA capability can only be used in conjunction with MSSP1. The SPI DMA feature is described in Section 20.4 "SPI DMA Module".

Note: In devices with more than one MSSP module, it is very important to pay close attention to SSPxCON register names. SSP1CON1 and SSP1CON2 control different operational aspects of the same module, while SSP1CON1 and SSP2CON1 control the same features for two different modules.

Note: The SSPxBUF register cannot be used with read-modify-write instructions, such as BCF, COMF, etc. To avoid lost data in Master mode, a read of the SSPxPUE must be per

read of the SSPxBUF must be performed to clear the Buffer Full (BF) detect bit (SSPSTAT<0>) between each transmission.

# 20.3 SPI Mode

The SPI mode allows 8 bits of data to be synchronously transmitted and received simultaneously. All four modes of SPI are supported. To accomplish communication, three pins are typically used. These pins must be assigned through the PPS-Lite Configuration registers before use.

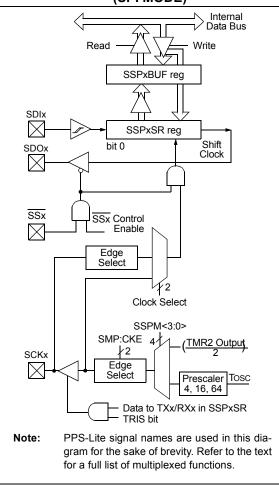

- Serial Data Out (SDOx) Mapped to pin using PPS-Lite Peripheral Output registers
- Serial Data In (SDIx) Mapped to pin using PPS-Lite Peripheral Input registers
- Serial Clock (SCKx) Mapped to pin using PPS-Lite Peripheral Input registers (for Slave mode) or Peripheral Output registers (for Master mode).

Additionally, a fourth pin may be used when in a Slave mode of operation:

 Slave Select (SSx) – Mapped through PPS-Lite Peripheral Input registers

Figure 20-1 shows the block diagram of the MSSPx module when operating in SPI mode.

#### FIGURE 20-1: MSSPx BLOCK DIAGRAM (SPI MODE)

#### 20.3.1 REGISTERS

Each MSSP module has four registers for SPI mode operation. These are:

- MSSPx Control Register 1 (SSPxCON1)
- MSSPx STATUS Register (SSPxSTAT)
- MSSPx Control Register 3 (SSPxCON3)
- Serial Receive/Transmit Buffer Register (SSPxBUF)
- MSSPx Shift Register (SSPxSR) Not directly accessible

SSPxCON1, SSPxCON3 and SSPxSTAT are the control and STATUS registers in SPI mode operation. The SSPxCON1 and SSPxCON3 registers are readable and writable. The lower 6 bits of the SSPxSTAT are read-only. The upper two bits of the SSPxSTAT are read/write. SSPxSR is the shift register used for shifting data in or out. SSPxBUF is the buffer register to which data bytes are written to or read from.

In receive operations, SSPxSR and SSPxBUF together, create a double-buffered receiver. When SSPxSR receives a complete byte, it is transferred to SSPxBUF and the SSPxIF interrupt is set.

During transmission, the SSPxBUF is not doublebuffered. A write to SSPxBUF will write to both SSPxBUF and SSPxSR.

				or to ignoro all l			

# REGISTER 20-3: SSPxCON3: MSSP CONTROL REGISTER 3 (SPI MODE)

2: For daisy-chained SPI operation; allows the user to ignore all but the last received byte. SSPOV is still set when a new byte is received and BF = 1, but hardware continues to write the most recent byte to SSPxBUF.

# 20.3.2 OPERATION

When initializing the SPI, several options need to be specified. This is done by programming the appropriate control bits (SSPxCON1<5:0> and SSPxSTAT<7:6>). These control bits allow the following to be specified:

- I/O pins must be mapped to the SPI peripheral in order to function. See Section 11.15 "PPS-Lite" for an explanation of the PPS-Lite mapping feature.
- Master mode (SCKx is the clock output)
- Slave mode (SCKx is the clock input)
- Clock Polarity (Idle state of SCKx)
- Data Input Sample Phase (middle or end of data output time)
- Clock Edge (output data on rising/falling edge of SCKx)
- Clock Rate (Master mode only)
- Slave Select mode (Slave mode only)

Each MSSPx module consists of a Transmit/Receive Shift register (SSPxSR) and a Buffer register (SSPxBUF). The SSPxSR shifts the data in and out of the device. MSb first. The SSPxBUF holds the data that was written to the SSPxSR until the received data is ready. Once the 8 bits of data have been received, that byte is moved to the SSPxBUF register. Then, the Buffer Full detect bit, BF (SSPxSTAT<0>), and the interrupt flag bit, SSPxIF, are set. This double-buffering of the received data (SSPxBUF) allows the next byte to start reception before reading the data that was just received. Any write to the SSPxBUF register during transmission/reception of data will be ignored and the Write Collision Detect bit, WCOL (SSPxCON1<7>), will be set. User software must clear the WCOL bit so that it can be determined if the following write(s) to the SSPxBUF register completed successfully.

When the application software is expecting to receive valid data, the SSPxBUF should be read before the next byte of data to transfer is written to the SSPxBUF. The Buffer Full bit, BF (SSPxSTAT<0>), indicates when SSPxBUF has been loaded with the received data (transmission is complete). When the SSPxBUF is read, the BF bit is cleared. This data may be irrelevant if the SPI is only a transmitter. Generally, the MSSPx interrupt is used to determine when the transmission/ reception has completed. If the interrupt method is not going to be used, then software polling can be done to ensure that a write collision does not occur. Example 20-1 shows the loading of the SSPxBUF (SSPxSR) for data transmission.

The SSPxSR is not directly readable or writable and can only be accessed by addressing the SSPxBUF register. Additionally, the SSPxSTAT register indicates the various status conditions.

# 20.3.3 OPEN-DRAIN OUTPUT OPTION

The drivers for the SDOx output and SCKx clock pins can be optionally configured as open-drain outputs. This feature allows the voltage level on the pin to be pulled to a higher level through an external pull-up resistor, and allows the output to communicate with external circuits without the need for additional level shifters. For more information, see Section 11.1.3 "Open-Drain Outputs".

The open-drain output option is controlled by the SSPxOD bits (ODCON1<1:0>). Setting an SSPxOD bit configures the SDOx and SCKx pins for the corresponding module for open-drain operation.

Note: To avoid lost data in Master mode, a read of the SSPxBUF must be performed to clear the Buffer Full (BF) detect bit (SSPxSTAT<0>) between each transmission.

# EXAMPLE 20-1: LOADING THE SSP1BUF (SSP1SR) REGISTER

	MOVF MOVWF	TXDATA, W SSP1BUF	;W reg = contents of TXDATA ;New data to xmit

#### 20.3.4 ENABLING SPI I/O

To enable the serial port, the peripheral must first be mapped to I/O pins using the PPS-Lite feature. To enable the SPI peripheral, the MSSPx Enable bit, SSPEN (SSPxCON1<5>) must be set. To reset or reconfigure SPI mode, clear the SSPEN bit, re-initialize the SSPxCON registers and then set the SSPEN bit. This configures the SDIx, SDOx, SCKx and SSx pins as serial port pins. For the pins to behave as the serial port function, some must have their data direction bits (in the TRIS register) appropriately programmed as follows:

- SDIx is automatically controlled by the SPI module
- SDOx must have the TRIS bit cleared for the corresponding RPn pin.
- SCKx (Master mode) must have the TRIS bit cleared for the corresponding RPn pin
- SCKx (Slave mode) must have the TRIS bit set for the corresponding RPn pin
- SSx must have the TRIS bit set for the corresponding RPn pin.

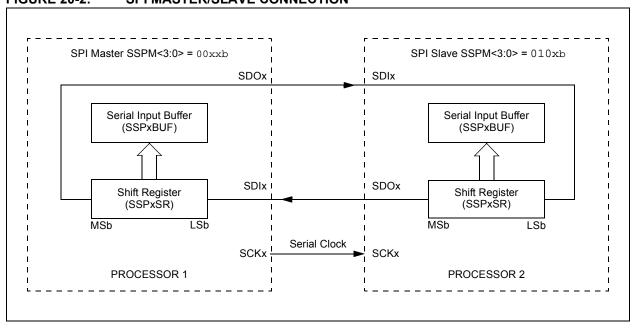

Any serial port function that is not desired may be overridden by programming the corresponding Data Direction (TRIS) register to the opposite value.

# FIGURE 20-2: SPI MASTER/SLAVE CONNECTION

#### 20.3.5 TYPICAL CONNECTION

Figure 20-2 shows a typical connection between two microcontrollers. The master controller (Processor 1) initiates the data transfer by sending the SCKx signal. Data is shifted out of both shift registers on their programmed clock edge and latched on the opposite edge of the clock. Both processors should be programmed to the same Clock Polarity (CKP), then both controllers would send and receive data at the same time. Whether the data is meaningful (or dummy data) depends on the application software. This leads to three scenarios for data transmission:

- · Master sends data Slave sends dummy data
- · Master sends data Slave sends data
- Master sends dummy data Slave sends data

# 20.3.6 MASTER MODE

The master can initiate the data transfer at any time because it controls the SCKx signal. The master determines when the slave (Processor 2, Figure 20-2) is to broadcast data by the software protocol.

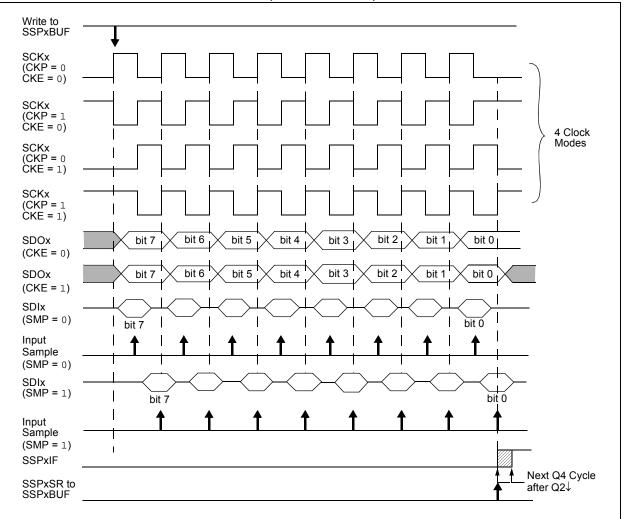

In Master mode, the data is transmitted/received as soon as the SSPxBUF register is written to. If the SPI is only going to receive, the SDOx output could be disabled (programmed as an input). The SSPxSR register will continue to shift in the signal present on the SDIx pin at the programmed clock rate. As each byte is received, it will be loaded into the SSPxBUF register as if a normal received byte (interrupts and Status bits appropriately set). This could be useful in receiver applications as a "Line Activity Monitor" mode.

The clock polarity is selected by appropriately programming the CKP bit (SSPxCON1<4>). This, then, would give waveforms for SPI communication, as shown in Figure 20-3, Figure 20-5 and Figure 20-6, where the MSB is transmitted first. In Master mode, the SPI clock rate (bit rate) is user-programmable to be one of the following:

- Fosc/4 (or Tcy)
- Fosc/(4 \* (SSPxADD + 1)
- Fosc/16 (or 4 Tcy)
- Fosc/64 (or 16 Tcy)
- Timer2 output/2

This allows a maximum data rate (at 64 MHz) of 16.00 Mbps.

Figure 20-3 shows the waveforms for Master mode. When the CKE bit is set, the SDOx data is valid before there is a clock edge on SCKx. The change of the input sample is shown based on the state of the SMP bit. The time when the SSPxBUF is loaded with the received data is shown.

# 20.3.7 SLAVE MODE

In Slave mode, the data is transmitted and received as the external clock pulses appear on SCKx. When the last bit is latched, the SSPxIF interrupt flag bit is set.

While in Slave mode, the external clock is supplied by the external clock source on the SCKx pin. This external clock must meet the minimum high and low times as specified in the electrical specifications.

While in Sleep mode, the slave can transmit/receive data. When a byte is received, the device can be configured to wake-up from Sleep.

#### 20.3.8 SLAVE SELECT SYNCHRONIZATION

The  $\overline{SSx}$  pin allows a Synchronous Slave mode. The SPI must be in Slave mode with the  $\overline{SSx}$  pin control enabled (SSPxCON1<3:0> = 04h). When the  $\overline{SSx}$  pin is low, transmission and reception are enabled and the SDOx pin is driven. When the  $\overline{SSx}$  pin goes high, the SDOx pin is no longer driven, even if in the middle of a

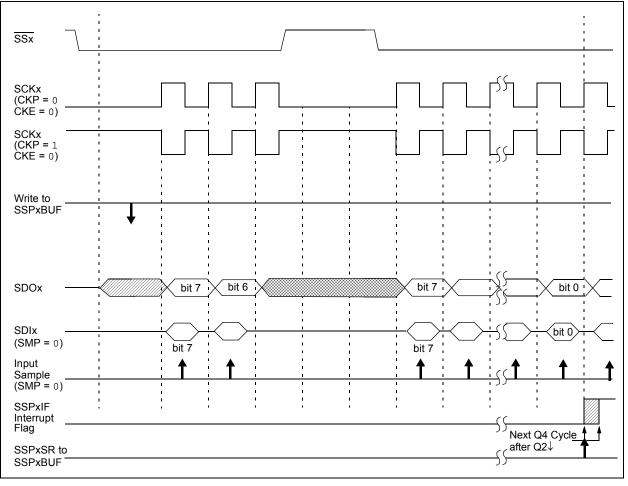

transmitted byte and becomes a floating output. External pull-up/pull-down resistors may be desirable depending on the application.

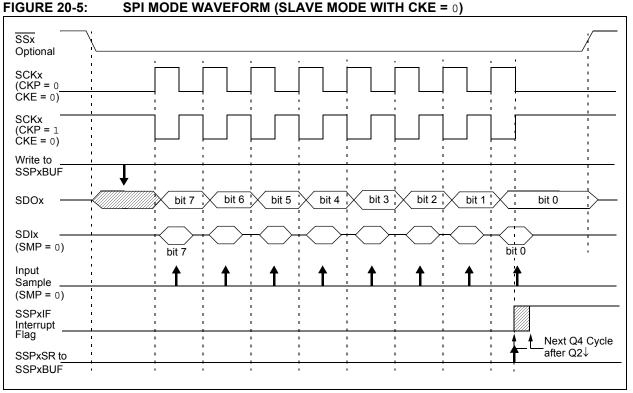

Note:	When the SPI is in Slave mode with
	SSx pin control enabled
	(SSPxCON1<3:0> = 0100), the SPI
	module will reset if the $\overline{SSx}$ pin is set to VDD.
	If the SPI is used in Slave mode with CKE set, then the SSx pin control must be enabled.

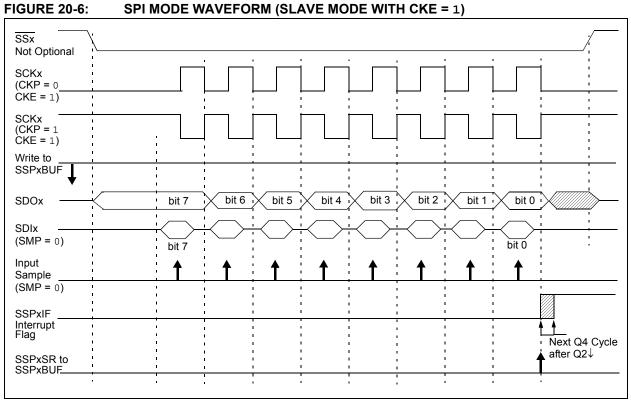

When the SPI module resets, the bit counter is forced to '0'. This can be done by either forcing the SSx pin to a high level or clearing the SSPEN bit.

To emulate two-wire communication, the SDOx pin can be connected to the SDIx pin. When the SPI needs to operate as a receiver, the SDOx pin can be configured as an input. This disables transmissions from the SDOx. The SDIx can always be left as an input (SDIx function) since it cannot create a bus conflict.

# FIGURE 20-4: SLAVE SYNCHRONIZATION WAVEFORM

#### 20.3.9 OPERATION IN POWER-MANAGED MODES

In SPI Master mode, module clocks may be operating at a different speed than when in full-power mode. In the case of Sleep mode, all clocks are halted.

In Idle modes, a clock is provided to the peripherals. That clock can be from the primary clock source, the secondary clock (SOSC Oscillator) or the INTOSC source.

In most cases, the speed that the master clocks SPI data is not important; however, this should be evaluated for each system.

If MSSPx interrupts are enabled, they can wake the controller from Sleep mode, or one of the Idle modes, when the master completes sending data. If an exit from Sleep or Idle mode is not desired, MSSPx interrupts should be disabled.

If the Sleep mode is selected, all module clocks are halted and the transmission/reception will remain in that state until the device wakes. After the device returns to Run mode, the module will resume transmitting and receiving data.

In SPI Slave mode, the SPI Transmit/Receive Shift register operates asynchronously to the device. This allows the device to be placed in any power-managed mode and data to be shifted into the SPI Transmit/ Receive Shift register. When all 8 bits have been received, the MSSPx interrupt flag bit will be set, and if enabled, will wake the device.

# 20.3.10 EFFECTS OF A RESET

A Reset disables the MSSPx module and terminates the current transfer.

# 20.3.11 BUS MODE COMPATIBILITY

Table 20-1shows the compatibility between thestandard SPI modes and the states of the CKP andCKE control bits.

#### TABLE 20-1: SPI BUS MODES

Standard SPI Mode	Control Bits State		
Terminology	СКР	CKE	
0,0	0	1	
0,1	0	0	
1,0	1	1	
1,1	1	0	

There is also an SMP bit which controls when the data is sampled.

# 20.3.12 SPI CLOCK SPEED AND MODULE INTERACTIONS

Because MSSP1 and MSSP2 are independent modules, they can operate simultaneously at different data rates. Setting the SSPM<3:0> bits of the SSPx-CON1 register determines the rate for the corresponding module.

An exception is when both modules use Timer2 as a time base in Master mode. In this instance, any changes to the Timer2 module's operation will affect both MSSPx modules equally. If different bit rates are required for each module, the user should select one of the other three time base options for one of the modules.

# 20.4 SPI DMA MODULE

The SPI DMA module contains control logic to allow the MSSP1 module to perform SPI Direct Memory Access transfers. This enables the module to quickly transmit or receive large amounts of data with relatively little CPU intervention. When the SPI DMA module is used, MSSP1 can directly read and write to general purpose SRAM. When the SPI DMA module is not enabled, MSSP1 functions normally, but without DMA capability.

The SPI DMA module is composed of control logic, a Destination Receive Address Pointer, a Transmit Source Address Pointer, an interrupt manager and a Byte Count register for setting the size of each DMA transfer. The DMA module may be used with all SPI Master and Slave modes, and supports both half-duplex and full-duplex transfers.

# 20.4.1 I/O PIN CONSIDERATIONS

When enabled, the SPI DMA module uses the MSSP1 module. All SPI input and output signals, related to MSSP1, are routed through the Peripheral Pin Select (PPS) module. The appropriate initialization procedure, as described in Section 20.4.6 "Using the SPI DMA Module", will need to be followed prior to using the SPI DMA module. The output pins assigned to the SDO and SCK functions can optionally be configured as open-drain outputs, such as for level shifting operations mentioned in the same section.

# 20.4.2 RAM TO RAM COPY OPERATIONS

Although the SPI DMA module is primarily intended to be used for SPI communication purposes, the module can also be used to perform RAM to RAM copy operations. To do this, configure the module for Full-Duplex Master mode operation, but assign the SDO output and SDI input functions onto the same RPn pin in the PPS-Lite module. Also assign SCK out and SCK in onto the same RPn pin (a different pin than used for SDO and SDI). This will allow the module to operate in Loopback mode, providing RAM copy capability.

# 20.4.3 IDLE AND SLEEP CONSIDERATIONS

The SPI DMA module remains fully functional when the microcontroller is in Idle mode.

During normal Sleep, the SPI DMA module is not functional and should not be used. To avoid corrupting a transfer, user firmware should be careful to make certain that pending DMA operations are complete by polling the DMAEN bit in the DMACON1 register, prior to putting the microcontroller into Sleep.

In SPI Slave modes, the MSSP1 module is capable of transmitting and/or receiving one byte of data while in Sleep mode. This allows the SSP1IF flag in the PIR1 register to be used as a wake-up source. When the DMAEN bit is cleared, the SPI DMA module is effectively disabled, and the MSSP1 module functions normally, but without DMA capabilities. If the DMAEN bit is clear prior to entering Sleep, it is still possible to use the SSP1IF as a wake-up source without any data loss.

Neither MSSP1 nor the SPI DMA module will provide any functionality in Deep Sleep. Upon exiting from Deep Sleep, all of the I/O pins, MSSP1 and SPI DMA related registers will need to be fully re-initialized before the SPI DMA module can be used again.

# 20.4.4 REGISTERS

The SPI DMA engine is enabled and controlled by the following Special Function Registers:

- DMACON1
   DMACON2
- TXADDRH
- RXADDRH
- DMABCH
- RXADDRLDMABCL

TXADDRL

#### 20.4.4.1 DMACON1

The DMACON1 register is used to select the main operating mode of the SPI DMA module. The SSCON1 and SSCON0 bits are used to control the slave select pin.

When MSSP1 is used in SPI Master mode with the SPI DMA module, SSDMA can be controlled by the DMA module as an output pin. If MSSP1 will be used to communicate with an SPI slave device that needs the SSx pin to be toggled periodically, the SPI DMA hardware can automatically be used to de-assert SSx between each byte, every two bytes or every four bytes.

Alternatively, user firmware can manually generate slave select signals with normal general purpose I/O pins, if required by the slave device(s).

When the TXINC bit is set, the TXADDR register will automatically increment after each transmitted byte. Automatic transmit address increment can be disabled by clearing the TXINC bit. If the automatic transmit address increment is disabled, each byte which is output on SDO will be the same (the contents of the SRAM pointed to by the TXADDR register) for the entire DMA transaction.

When the RXINC bit is set, the RXADDR register will automatically increment after each received byte. Automatic receive address increment can be disabled by clearing the RXINC bit. If RXINC is disabled in Full-Duplex or Half-Duplex Receive modes, all incoming data bytes on SDI will overwrite the same memory location pointed to by the RXADDR register. After the SPI DMA transaction has completed, the last received byte will reside in the memory location pointed to by the RXADDR register.

The SPI DMA module can be used for either half-duplex receive only communication, half-duplex transmit only communication or full-duplex simultaneous transmit and receive operations. All modes are available for both SPI master and SPI slave configurations. The DUPLEX0 and DUPLEX1 bits can be used to select the desired operating mode.

The behavior of the DLYINTEN bit varies greatly depending on the SPI operating mode. For example behavior for each of the modes, see Figure 20-3 through Figure 20-6.

**SPI Slave mode, DLYINTEN = 1:** In this mode, an SSP1IF interrupt will be generated during a transfer if the time between successful byte transmission events is longer than the value set by the DLYCYC<3:0> bits in the DMACON2 register. This interrupt allows slave firmware to know that the master device is taking an unusually large amount of time between byte transmissions. For example, this information may be useful for implementing application defined communication protocols, involving time-outs if the bus remains Idle for

too long. When DLYINTEN = 1, the DLYLVL<3:0> interrupts occur normally according to the selected setting.

**SPI Slave mode, DLYINTEN =** 0: In this mode, the time-out based interrupt is disabled. No additional SSP1IF interrupt events will be generated by the SPI DMA module, other than those indicated by the INTLVL<3:0> bits in the DMACON2 register. In this mode, always set DLYCYC<3:0> = 0000.

**SPI Master mode, DLYINTEN = 0:** The DLYCYC<3:0> bits in the DMACON2 register determine the amount of additional inter-byte delay, which is added by the <u>SPI</u> DMA module during a transfer; the Master mode <u>SS1</u> output feature may be used.

**SPI Master mode, DLYINTEN = 1:** The amount of hardware overhead is slightly reduced in this mode, and the minimum inter-byte delay is 8 TcY for FOSC/4, 9 TcY for FOSC/16 and 15 TcY for FOSC/64. This mode can potentially be used to obtain slightly higher effective SPI bandwidth. In this mode, the SS1 control feature cannot be used and should always be disabled (DMACON1<7:6> = 00). Additionally, the interrupt generating hardware (used in Slave mode) remains active. To avoid extraneous SSP1IF interrupt events, set the DMACON2 Delay bits, DLYCYC<3:0> = 1111, and ensure that the SPI serial clock rate is no slower than FOSC/64.

In SPI Master modes, the DMAEN bit is used to enable the SPI DMA module and to initiate an SPI DMA transaction. After user firmware sets the DMAEN bit, the DMA hardware will begin transmitting and/or receiving data bytes according to the configuration used. In SPI Slave modes, setting the DMAEN bit will finish the initialization steps needed to prepare the SPI DMA module for communication (which must still be initiated by the master device).

To avoid possible data corruption, once the DMAEN bit is set, user firmware should not attempt to modify any of the MSSP2 or SPI DMA related registers, with the exception of the INTLVLx bits in the DMACON2 register.

If user firmware wants to halt an ongoing DMA transaction, the DMAEN bit can be manually cleared by the firmware. Clearing the DMAEN bit while a byte is currently being transmitted will not immediately halt the byte in progress. Instead, any byte currently in progress will be completed before the MSSP1 and SPI DMA modules go back to their Idle conditions. If user firmware clears the DMAEN bit, the TXADDR, RXADDR and DMABC registers will no longer update, and the DMA module will no longer make any additional read or writes to SRAM; therefore, state information can be lost.

#### REGISTER 20-4: DMACON1: DMA CONTROL REGISTER 1

#### 20.4.4.2 DMACON2

The DMACON2 register contains control bits for controlling interrupt generation and inter-byte delay behavior. The INTLVL<3:0> bits are used to select when an SSP1IF interrupt should be generated. The function of the DLYCYC<3:0> bits depends on the SPI operating mode (Master/Slave), as well as the DLYINTEN setting. In SPI Master mode, the DLYCYC<3:0> bits can be used to control how much time the module will Idle between bytes in a transfer. By default, the hardware requires a minimum delay of 8 TcY for FOSC/4, 9 TcY for FOSC/16 and 15 TcY for FOSC/64. An additional delay can be added with the DLYCYCx bits. In SPI Slave modes, the DLYCYC<3:0> bits may optionally be used to trigger an additional time-out based interrupt.

0000 = Transfer complete

### 20.4.4.3 DMABCH and DMABCL

The DMABCH and DMABCL register pair forms a 10-bit Byte Count register, which is used by the SPI DMA module to send/receive up to 1,024 bytes for each DMA transaction. When the DMA module is actively running (DMAEN = 1), the DMA Byte Count register decrements after each byte is transmitted/received. The DMA transaction will halt and the DMAEN bit will be automatically cleared by hardware after the last byte has completed. After a DMA transaction is complete, the DMABC register will read 0x000.

Prior to initiating a DMA transaction by setting the DMAEN bit, user firmware should load the appropriate value into the DMABCH/DMABCL registers. The DMABC is a "base zero" counter, so the actual number of bytes which will be transmitted follows in Equation 20-1.

For example, if user firmware wants to transmit 7 bytes in one transaction, DMABC should be loaded with 006h. Similarly, if user firmware wishes to transmit 1,024 bytes, DMABC should be loaded with 3FFh.

### EQUATION 20-1: BYTES TRANSMITTED FOR A GIVEN DMABC

Bytes<sub>XMIT</sub> ½ (DMABC + 1)

### 20.4.4.4 TXADDRH and TXADDRL

The TXADDRH and TXADDRL registers pair together to form a 12-bit Transmit Source Address Pointer register. In modes that use TXADDR (Full-Duplex and Half-Duplex Transmit), the TXADDR will be incremented after each byte is transmitted. Transmitted data bytes will be taken from the memory location pointed to by the TXADDR register. The contents of the memory locations pointed to by TXADDR will not be modified by the DMA module during a transmission.

The SPI DMA module can read from, and transmit data from, all general purpose memory on the device, including memory used for USB endpoint buffers. The SPI DMA module cannot be used to read from the Special Function Registers (SFRs) contained in Banks 14 and 15.

### 20.4.4.5 RXADDRH and RXADDRL

The RXADDRH and RXADDRL registers pair together to form a 12-bit Receive Destination Address Pointer. In modes that use RXADDR (Full-Duplex and Half-Duplex Receive), the RXADDR register will be incremented after each byte is received. Received data bytes will be stored at the memory location pointed to by the RXADDR register. The SPI DMA module can write received data to all general purpose memory on the device, including memory used for USB endpoint buffers. The SPI DMA module cannot be used to modify the Special Function Registers contained in Banks 14 and 15.

### 20.4.5 INTERRUPTS

The SPI DMA module alters the behavior of the SSP1IF interrupt flag. In normal non-DMA modes, the SSP1IF is set once after every single byte is transmitted/received through the MSSP1 module. When MSSP1 is used with the SPI DMA module, the SSP1IF interrupt flag will be set according to the user-selected INTLVL<3:0> value specified in the DMACON2 register. The SSP1IF interrupt condition will also be generated once the SPI DMA transaction has fully completed and the DMAEN bit has been cleared by hardware.

The SSP1IF flag becomes set once the DMA byte count value indicates that the specified INTLVLx has been reached. For example, if DMACON2<3:0> = 0101 (16 bytes remaining), the SSP1IF interrupt flag will become set once DMABC reaches 00Fh. If user firmware then clears the SSP1IF interrupt flag, the flag will not be set again by the hardware until after all bytes have been fully transmitted and the DMA transaction is complete.

**Note:** User firmware may modify the INTLVLx bits while a DMA transaction is in progress (DMAEN = 1). If an INTLVLx value is selected which is higher than the actual remaining number of bytes (indicated by DMABC + 1), the SSP1IF interrupt flag will immediately become set.

For example, if DMABC = 00Fh (implying 16 bytes are remaining) and user firmware writes '1111' to INTLVL<3:0> (interrupt when 576 bytes are remaining), the SSP1IF interrupt flag will immediately become set. If user firmware clears this interrupt flag, a new interrupt condition will not be generated until either: user firmware again writes INTLVLx with an interrupt level higher than the actual remaining level, or the DMA transaction completes and the DMAEN bit is cleared.

**Note:** If the INTLVLx bits are modified while a DMA transaction is in progress, care should be taken to avoid inadvertently changing the DLYCYC<3:0> value.

### 20.4.6 USING THE SPI DMA MODULE

The following steps would typically be taken to enable and use the SPI DMA module:

- 1. Configure the I/O pins, which will be used by MSSP2:
  - a) Assign SCK1, SDO1, SDI1 and SS1 to the RPn pins, as appropriate for the SPI mode which will be used. Only functions which will be used need to be assigned to a pin.
  - b) Initialize the associated LATx registers for the desired Idle SPI bus state.
  - c) If Open-Drain Output mode on SDO1 and SCK1 (Master mode) is desired, set ODCON1<1>.
  - d) Configure the corresponding TRISx bits for each I/O pin used.
- 2. Configure and enable MSSP1 for the desired SPI operating mode:
  - a) Select the desired operating mode (Master or Slave, SPI Mode 0, 1, 2 and 3) and configure the module by writing to the SSP1STAT and SSP1CON1 registers.
  - b) Enable MSSP1 by setting SSP1CON1<5> = 1.
- 3. Configure the SPI DMA engine:
  - a) Select the desired operating mode by writing the appropriate values to DMA-CON2 and DMACON1.
  - b) Initialize the TXADDRH/TXADDRL Pointer (Full-Duplex or Half-Duplex Transmit Only mode).
  - c) Initialize the RXADDRH/RXADDRL Pointer (Full-Duplex or Half-Duplex Receive Only mode).
  - d) Initialize the DMABCH/DMABCL Byte Count register with the number of bytes to be transferred in the next SPI DMA operation.
  - e) Set the DMAEN bit (DMACON1<0>).

In SPI Master modes, this will initiate a DMA transaction. In SPI Slave modes, this will complete the initialization process, and the module will now be ready to begin receiving and/or transmitting data to the master device once the master starts the transaction.

- 4. Detect the SSP1IF interrupt condition (PIR1<3):
  - a) If the interrupt was configured to occur at the completion of the SPI DMA transaction, the DMAEN bit (DMACON1<0>) will be clear. User firmware may prepare the module for another transaction by repeating Steps 3.b through 3.e.
  - b) If the interrupt was configured to occur prior to the completion of the SPI DMA transaction, the DMAEN bit may still be set,

indicating the transaction is still in progress. User firmware would typically use this interrupt condition to begin preparing new data for the next DMA transaction. Firmware should not repeat Steps 3.b. through 3.e. until the DMAEN bit is cleared by the hardware, indicating the transaction is complete.

Example 20-3 provides example code, demonstrating the initialization process and the steps needed to use the SPI DMA module to perform a 512-byte Full-Duplex Master mode transfer.

### EXAMPLE 20-2: 512-BYTE SPI MASTER MODE INIT AND TRANSFER

		;For this example, let's use RP3(RA3) for SCK1, ;RP1(RA1) for SD01, and RP0(RA0) for SDI1
		;Let's use SPI master mode, CKE = 0, CKP = 0, ;without using slave select signalling.

		;Somewhere else in our project, lets assume we have ;allocated some RAM for use as SPI receive and ;transmit buffers.

EXAMPLE 20-2:	512-BYTE SPI MASTER MODE INIT AND TRANSFER (CONTINUED)
---------------	--

; ;DestBuf ;	udata res	0x500 0x200	;Let's reserve 0x500-0x6FF for use as our SPI ;receive data buffer in this example
; ;SrcBuf ;	res	0x200	;Lets reserve 0x700-0x8FF for use as our SPI ;transmit data buffer in this example
PrepareTra	nsfer:		
	movlw	HIGH(DestBuf)	;Get high byte of DestBuf address (0x05)
	movwf		;Load upper four bits of the RXADDR register
		LOW(DestBuf) RXADDRL	;Get low byte of the DestBuf address (0x00) ;Load lower eight bits of the RXADDR register
	movlw	HIGH(SrcBuf)	;Get high byte of SrcBuf address (0x07)
	movwf		;Load upper four bits of the TXADDR register
	movlw movwf	,	;Get low byte of the SrcBuf address (0x00) ;Load lower eight bits of the TXADDR register
	movlw	0x01	;Lets move 0x200 (512) bytes in one DMA xfer
	movwf	DMABCH	;Load the upper two bits of DMABC register
	movlw	OxFF	;Actual bytes transferred is (DMABC + 1), so
	movwf	DMABCL	;we load $0x01FF$ into DMABC to xfer $0x200$ bytes
BeginXfer:			
	bsf	DMACON1, DMAEN	;The SPI DMA module will now begin transferring ;the data taken from SrcBuf, and will store ;received bytes into DestBuf.
;Execu	te whate	ever	;CPU is now free to do whatever it wants to
			;and the DMA operation will continue without
			; intervention, until it completes.
			;When the transfer is complete, the SSP2IF flag in ;the PIR3 register will become set, and the DMAEN bit ;is automatically cleared by the hardware. ;The DestBuf (0x500-0x7FF) will contain the received ;data. To start another transfer, firmware will need ;to reinitialize RXADDR, TXADDR, DMABC and then ;set the DMAEN bit.

### 20.5 I<sup>2</sup>C Mode

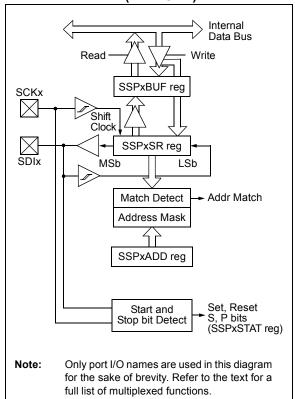

The MSSPx module in  $I^2C$  mode fully implements all master and slave functions (including general call support), and provides interrupts on Start and Stop bits in hardware to determine a free bus (multi-master function). The MSSPx module implements the standard mode specifications, as well as 7-bit and 10-bit addressing.

Two pins are used for data transfer:

- Serial Clock (SCLx) RC3/SCL1 or RD6/SCL2
- Serial Data (SDAx) RC4/SDA1 or RD5/SDA2

The user must configure these pins as inputs by setting the associated TRIS bits.

### FIGURE 20-7: MSSPx BLOCK DIAGRAM (I<sup>2</sup>C MODE)

### 20.5.1 REGISTERS

The MSSPx module has seven registers for  ${\rm I}^2{\rm C}$  operation. These are:

- MSSPx Control Register 1 (SSPxCON1)
- MSSPx Control Register 2 (SSPxCON2)
- MSSPx Control Register 3 (SSPxCON3)
- MSSPx STATUS Register (SSPxSTAT)
- Serial Receive/Transmit Buffer Register (SSPxBUF)
- MSSPx Shift Register (SSPxSR) Not directly accessible
- MSSPx Address Register (SSPxADD)
- I<sup>2</sup>C Slave Address Mask Register (SSPxMSK)

SSPxCON1, SSPxCON2, SSPxCON3 and SSPxSTAT are the control and STATUS registers in I<sup>2</sup>C mode operation. The SSPxCON1, SSPxCON2, and SSPx-CON3 registers are readable and writable. The lower 6 bits of the SSPxSTAT are read-only. The upper two bits of the SSPxSTAT are read/write.

SSPxSR is the shift register used for shifting data in or out. SSPxBUF is the buffer register to which data bytes are written to or read from.

SSPxADD contains the slave device address when the MSSPx is configured in I<sup>2</sup>C Slave mode. When the MSSPx is configured in Master mode, the lower seven bits of SSPxADD act as the Baud Rate Generator reload value.

SSPxMSK holds the slave address mask value when the module is configured for 7-Bit Address Masking mode. While it is a separate register, it shares the same SFR address as SSPxADD; it is only accessible when the SSPM<3:0> bits are specifically set to permit access. Additional details are provided in Section 20.5.4.3 "7-Bit Address Masking Mode".

In receive operations, SSPxSR and SSPxBUF together, create a double-buffered receiver. When SSPxSR receives a complete byte, it is transferred to SSPxBUF and the SSPxIF interrupt is set.

During transmission, the SSPxBUF is not doublebuffered. A write to SSPxBUF will write to both SSPxBUF and SSPxSR.

bit 7-0 MSK<7:0>: Slave Address Mask Select bits

- 1 = Masking of corresponding bit of SSPxADD is enabled
- 0 = Masking of corresponding bit of SSPxADD is disabled
- Note 1: This register shares the same SFR address as SSPxADD and is only addressable in select MSSPx operating modes. See Section 20.5.4.3 "7-Bit Address Masking Mode" for more details.
  - **2:** MSK0 is not used as a mask bit in 7-bit addressing.

### 20.5.2 OPERATION

The MSSPx module functions are enabled by setting the MSSPx Enable bit, SSPEN (SSPxCON1<5>).

The SSPxCON1 register allows control of the  $I^2C$  operation. Four mode selection bits (SSPxCON1<3:0>) allow one of the following  $I^2C$  modes to be selected:

- I<sup>2</sup>C Master mode, clock
- I<sup>2</sup>C Slave mode (7-bit address)
- I<sup>2</sup>C Slave mode (10-bit address)
- I<sup>2</sup>C Slave mode (7-bit address) with Start and Stop bit interrupts enabled
- I<sup>2</sup>C Slave mode (10-bit address) with Start and Stop bit interrupts enabled
- I<sup>2</sup>C Firmware Controlled Master mode, slave is Idle

Selection of any I<sup>2</sup>C mode, with the SSPEN bit set, forces the SCLx and SDAx pins to be open-drain, provided these pins are programmed as inputs by setting the appropriate TRISC or TRISD bits. To ensure proper operation of the module, pull-up resistors must be provided externally to the SCLx and SDAx pins.

### 20.5.3 SLAVE MODE

In Slave mode, the SCLx and SDAx pins must be configured as inputs (TRISC<4:3> set). The MSSPx module will override the input state with the output data when required (slave-transmitter).

The  $I^2C$  Slave mode hardware will always generate an interrupt on an address match. Address masking will allow the hardware to generate an interrupt for more than one address (up to 31 in 7-bit addressing and up to 63 in 10-bit addressing). Through the mode select bits, the user can also choose to interrupt on Start and Stop bits.

When an address is matched, or the data transfer after an address match is received, the hardware automatically will generate the Acknowledge (ACK) pulse and load the SSPxBUF register with the received value currently in the SSPxSR register.

Any combination of the following conditions will cause the MSSPx module not to give this ACK pulse:

- The Buffer Full bit, BF (SSPxSTAT<0>), was set before the transfer was received.
- The overflow bit, SSPOV (SSPxCON1<6>), was set before the transfer was received.

In this case, the SSPxSR register value is not loaded into the SSPxBUF, but bit, SSPxIF, is set. The BF bit is cleared by reading the SSPxBUF register, while bit, SSPOV, is cleared through software.

The SCLx clock input must have a minimum high and low for proper operation. The high and low times of the  $I^2C$  specification, as well as the requirement of the MSSPx module, are shown in timing Parameter 100 and Parameter 101.

### 20.5.4 ADDRESSING

Once the MSSPx module has been enabled, it waits for a Start condition to occur. Following the Start condition, the 8 bits are shifted into the SSPxSR register. All incoming bits are sampled with the rising edge of the clock (SCLx) line. The value of register, SSPxSR<7:1>, is compared to the value of the SSPxADD register. The address is compared on the falling edge of the eighth clock (SCLx) pulse. If the addresses match, and the BF and SSPOV bits are clear, the following events occur:

- 1. The SSPxSR register value is loaded into the SSPxBUF register.
- 2. The Buffer Full bit, BF, is set.
- 3. An ACK pulse is generated.
- 4. The MSSPx Interrupt Flag bit, SSPxIF, is set (and interrupt is generated if enabled) on the falling edge of the ninth SCLx pulse.

In 10-Bit Addressing mode, two address bytes need to be received by the slave. The five Most Significant bits (MSbs) of the first address byte specify if this is a 10-bit address. The  $R/\overline{W}$  (SSPxSTAT<2>) bit must specify a write so the slave device will receive the second address byte. For a 10-bit address, the first byte would equal '11110 A9 A8 0', where 'A9' and 'A8' are the two MSbs of the address. The sequence of events for 10-bit addressing is as follows, with Steps 7 through 9 for the slave-transmitter:

- 1. Receive first (high) byte of address (bits, SSPxIF, BF and UA, are set on address match).
- 2. Update the SSPxADD register with second (low) byte of address (clears bit, UA, and releases the SCLx line).
- 3. Read the SSPxBUF register (clears bit, BF) and clear flag bit, SSPxIF.
- 4. Receive second (low) byte of address (bits, SSPxIF, BF and UA, are set).
- 5. Update the SSPxADD register with the first (high) byte of address. If match releases SCLx line, this will clear bit, UA.
- 6. Read the SSPxBUF register (clears bit, BF) and clear flag bit SSPxIF.
- 7. Receive Repeated Start condition.
- 8. Receive first (high) byte of address (bits, SSPxIF and BF, are set).
- 9. Read the SSPxBUF register (clears bit, BF) and clear flag bit, SSPxIF.

### 20.5.4.1 Address Masking Modes

Masking an address bit causes that bit to become a "don't care". When one address bit is masked, two addresses will be Acknowledged and cause an interrupt. It is possible to mask more than one address bit at a time, which greatly expands the number of addresses Acknowledged.

The  $l^2C$  slave behaves the same way, whether address masking is used or not. However, when address masking is used, the  $l^2C$  slave can Acknowledge multiple addresses and cause interrupts. When this occurs, it is necessary to determine which address caused the interrupt by checking the SSPxBUF.

The PIC18FXXJ94 of devices is capable of using two different Address Masking modes in I<sup>2</sup>C slave operation: 5-Bit Address Masking and 7-Bit Address Masking. The Masking mode is selected at device configuration using the MSSPMSK<2:1> Configuration bits. The default device configuration is 7-Bit Address Masking.

Both Masking modes, in turn, support address masking of 7-bit and 10-bit addresses. The combination of Masking modes and addresses provides different ranges of Acknowledgable addresses for each combination.

While both Masking modes function in roughly the same manner, the way they use address masks are different.

### 20.5.4.2 5-Bit Address Masking Mode

As the name implies, 5-Bit Address Masking mode uses an address mask of up to 5 bits to create a range of addresses to be Acknowledged, using bits, 5 through 1, of the incoming address. This allows the module to Acknowledge up to 31 addresses when using 7-bit addressing, or 63 addresses with 10-bit addressing (see Example 20-3). This Masking mode is selected when the MSSPMSK<2:1> Configuration bits are programmed ('00').

The address mask in this mode is stored in the SSPx-CON2 register, which stops functioning as a control register in I<sup>2</sup>C Slave mode (Register 20-10). In 7-Bit Address Masking mode, Address Mask bits, MSK<5:1> (SSPxMSK<5:1>), mask the corresponding address bits in the SSPxADD register. For any MSK bits that are set (MSK<n> = 1), the corresponding address bit is ignored (SSPxADD<n> = x). For the module to issue an address Acknowledge, it is sufficient to match only on addresses that do not have an active address mask.

In 10-Bit Address Masking mode, the MSK<5:2> bits mask the corresponding address bits in the SSPxADD register. In addition, MSK1 simultaneously masks the two LSbs of the address (SSPxADD<1:0>). For any MSKx bits that are active (MSK<n> = 1), the corresponding address bit is ignored (SPxADD<n> = x). Also note that although in 10-Bit Address Masking mode, the upper address bits re-use part of the SSPxADD register bits. The address mask bits do not interact with those bits; they only affect the lower address bits.

- Note 1: MSK1 masks the two Least Significant bits of the address.
  - The two Most Significant bits of the address are not affected by address masking.

### EXAMPLE 20-3: ADDRESS MASKING EXAMPLES IN 5-BIT MASKING MODE

### 7-Bit Addressing:

SSPxADD<7:1>= A0h (1010000) (SSPxADD<0> is assumed to be '0')

### MSK<5:1>= 00111

Addresses Acknowledged: A0h, A2h, A4h, A6h, A8h, AAh, ACh, AEh

### 10-Bit Addressing:

SSPxADD<7:0> = A0h (10100000) (The two MSb of the address are ignored in this example, since they are not affected by masking.)

MSK<5:1> = 00111

Addresses Acknowledged: A0h, A1h, A2h, A3h, A4h, A5h, A6h, A7h, A8h, A9h, AAh, ABh, ACh, ADh, AEh, AFh

### 20.5.4.3 7-Bit Address Masking Mode

Unlike 5-bit masking, 7-Bit Address Masking mode uses a mask of up to 8 bits (in 10-bit addressing) to define a range of addresses that can be Acknowledged, using the lowest bits of the incoming address. This allows the module to Acknowledge up to 127 different addresses with 7-bit addressing, or 255 with 10-bit addressing (see Example 20-4). This mode is the default configuration of the module, which is selected when MSSPMSK<2:1> are unprogrammed ('1').

The address mask for 7-Bit Address Masking mode is stored in the SSPxMSK register, instead of the SSPx-CON2 register. SSPxMSK is a separate hardware register within the module, but it is not directly addressable. Instead, it shares an address in the SFR space with the SSPxADD register. To access the SSPxMSK register, it is necessary to select MSSP mode, '1001' (SSPxCON1<3:0> = 1001) and then read or write to the location of SSPxADD.

To use 7-Bit Address Masking mode, it is necessary to initialize SSPxMSK with a value before selecting the  $I^2C$  Slave Addressing mode. Thus, the required sequence of events is:

- Select SSPxMSK Access mode (SSPx-CON2<3:0> = 1001).
- 2. Write the mask value to the appropriate SSPxADD register address (FC8h for MSSP1, F6Eh for MSSP2).
- Set the appropriate I<sup>2</sup>C Slave mode (SSPx-CON2<3:0> = 0111 for 10-bit addressing, 0110 for 7-bit addressing).

Setting or clearing mask bits in SSPxMSK behaves in the opposite manner of the MSKx bits in 5-Bit Address Masking mode. That is, clearing a bit in SSPxMSK causes the corresponding address bit to be masked; setting the bit requires a match in that position. SSPxMSK resets to all '1's upon any Reset condition, and therefore, has no effect on the standard MSSP operation until written with a mask value.

With 7-bit addressing, SSPxMSK<7:1> bits mask the corresponding address bits in the SSPxADD register. For any SSPxMSK bits that are active (SSPxMSK<n> = 0), the corresponding SSPxADD address bit is ignored (SSPxADD<n> = x). For the module to issue an address Acknowledge, it is sufficient to match only on addresses that do not have an active address mask.

With 10-bit addressing, SSPxMSK<7:0> bits mask the corresponding address bits in the SSPxADD register. For any SSPxMSK bits that are active (= 0), the corresponding SSPxADD address bit is ignored (SSPxADD<br/>n = x).

Note: The two Most Significant bits of the address are not affected by address masking.

### EXAMPLE 20-4: ADDRESS MASKING EXAMPLES IN 7-BIT MASKING MODE

### 7-Bit Addressing:

SSPxADD<7:1> = 1010 000

SSPxMSK<7:1> = 1111 001

Addresses Acknowledged = ACh, A8h, A4h, A0h

### 10-Bit Addressing:

SSPxADD<7:0> = 1010 0000 (The two MSb are ignored in this example since they are not affected)

SSPxMSK<5:1> = 1111 0011

Addresses Acknowledged = ACh, A8h, A4h, A0h

### 20.5.5 RECEPTION

When the  $R/\overline{W}$  bit of the address byte is clear and an address match occurs, the  $R/\overline{W}$  bit of the SSPxSTAT register is cleared. The received address is loaded into the SSPxBUF register and the SDAx line is held low (ACK).

When the address byte overflow condition exists, then the no Acknowledge (ACK) pulse is given. An overflow condition is defined if either bit, BF (SSPxSTAT<0>), is set or bit, SSPOV (SSPxCON1<6>), is set.

An MSSPx interrupt is generated for each data transfer byte. The interrupt flag bit, SSPxIF, must be cleared in software. The SSPxSTAT register is used to determine the status of the byte.

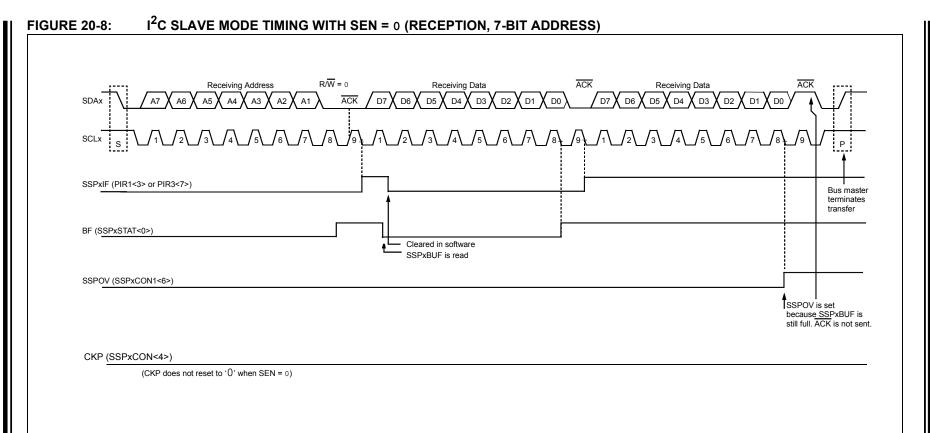

If SEN is enabled (SSPxCON2<0> = 1), SCLx will be held low (clock stretch) following each data transfer. The clock must be released by setting bit, CKP (SSPx-CON1<4>). See **Section 20.5.7 "Clock Stretching"** for more details.

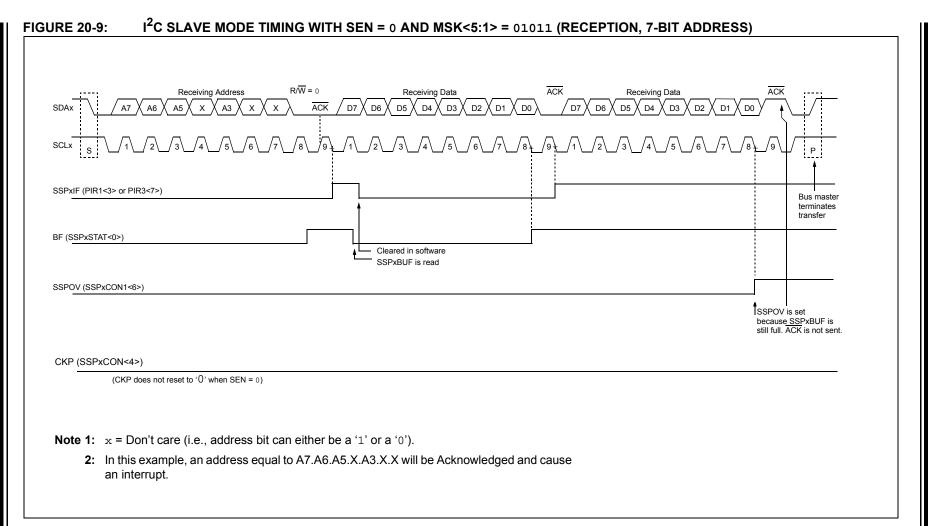

### 20.5.6 TRANSMISSION

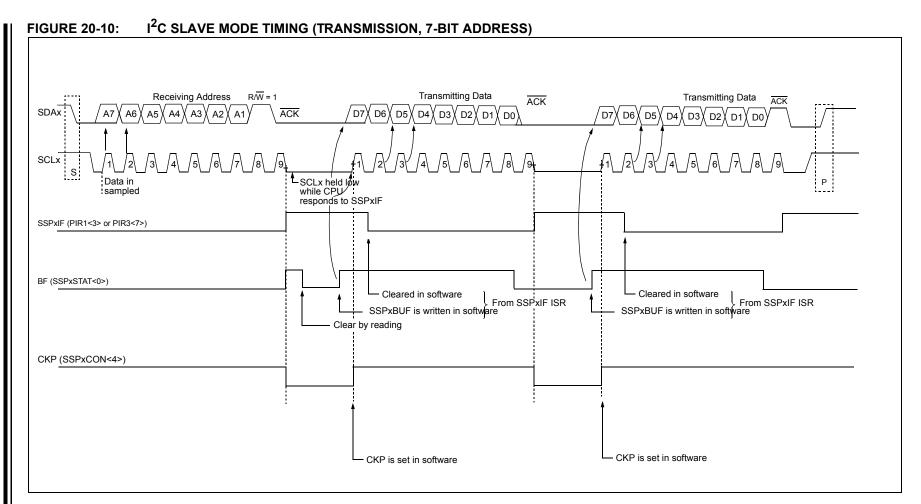

When the R/W bit of the incoming address byte is set and an address match occurs, the R/W bit of the SSPxSTAT register is set. The received address is loaded into the SSPxBUF register. The ACK pulse will be sent on the ninth bit and pin, SCLx, is held low regardless of SEN (see Section 20.5.7 "Clock Stretching" for more details). By stretching the clock, the master will be unable to assert another clock pulse until the slave is done preparing the transmit data. The transmit data must be loaded into the SSPxBUF register which also loads the SSPxSR register. Then, pin, SCLx, should be enabled by setting bit, CKP (SSPx-CON1<4>). The eight data bits are shifted out on the falling edge of the SCLx input. This ensures that the SDAx signal is valid during the SCLx high time (Figure 20-10).

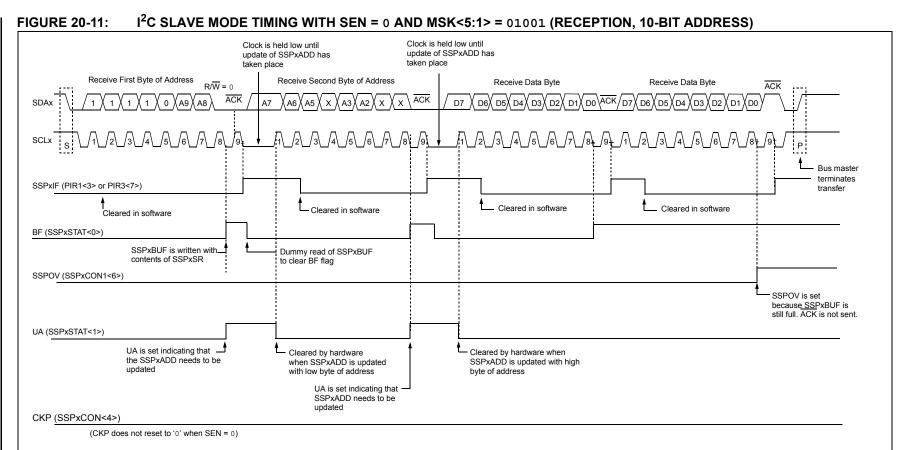

The  $\overline{ACK}$  pulse from the master-receiver is latched on the rising edge of the ninth SCLx input pulse. If the SDAx line is high (not  $\overline{ACK}$ ), then the data transfer is complete. In this case, when the  $\overline{ACK}$  is latched by the slave, the slave logic is reset and the slave monitors for another occurrence of the Start bit. If the SDAx line was low ( $\overline{ACK}$ ), the next transmit data must be loaded into the SSPxBUF register. Again, pin SCLx must be enabled by setting bit, CKP.

An MSSPx interrupt is generated for each data transfer byte. The SSPxIF bit must be cleared in software and the SSPxSTAT register is used to determine the status of the byte. The SSPxIF bit is set on the falling edge of the ninth clock pulse.

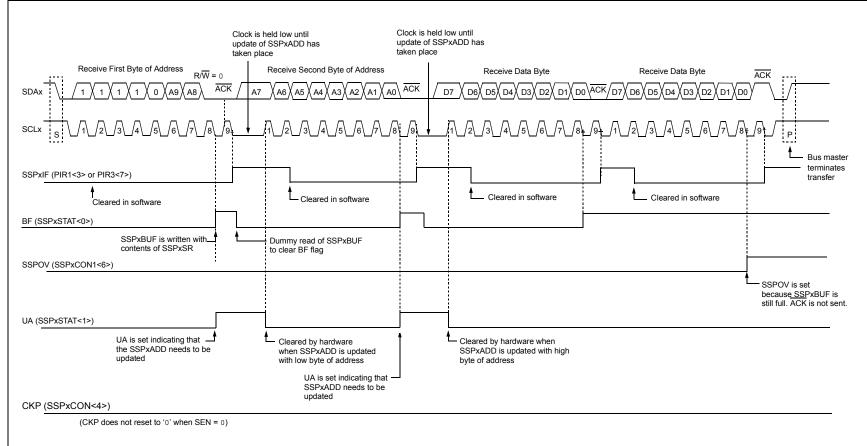

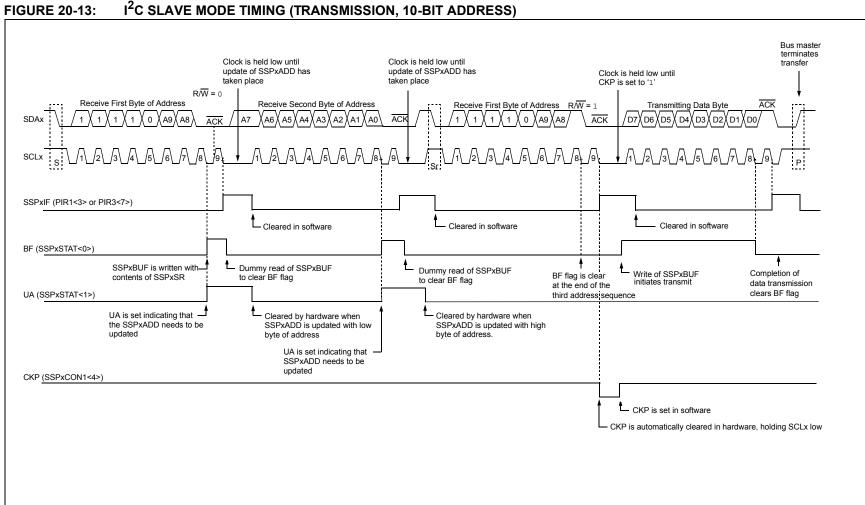

Note 1: x = Don't care (i.e., address bit can either be a '1' or a '0').

- 2: In this example, an address equal to A9.A8.A7.A6.A5.X.A3.A2.X.X will be Acknowledged and cause an interrupt.
- 3: Note that the Most Significant bits of the address are not affected by the bit masking.

### 20.5.7 CLOCK STRETCHING

Both 7-Bit and 10-Bit Slave modes implement automatic clock stretching during a transmit sequence.

The SEN bit (SSPxCON2<0>) allows clock stretching to be enabled during receives. Setting SEN will cause the SCLx pin to be held low at the end of each data receive sequence.

### 20.5.7.1 Clock Stretching for 7-Bit Slave Receive Mode (SEN = 1)

In 7-Bit Slave Receive mode, on the falling edge of the ninth clock at the end of the ACK sequence, if the BF bit is set, the CKP bit in the SSPxCON1 register is automatically cleared, forcing the SCLx output to be held low. The CKP bit, being cleared to '0', will assert the SCLx line low. The CKP bit must be set in the user's ISR before reception is allowed to continue. By holding the SCLx line low, the user has time to service the ISR and read the contents of the SSPxBUF before the master device can initiate another receive sequence. This will prevent buffer overruns from occurring (see Figure 20-15).

- Note 1: If the user reads the contents of the SSPxBUF before the falling edge of the ninth clock, thus clearing the BF bit, the CKP bit will not be cleared and clock stretching will not occur.
  - 2: The CKP bit can be set in software regardless of the state of the BF bit. The user should be careful to clear the BF bit in the ISR before the next receive sequence in order to prevent an overflow condition.

### 20.5.7.2 Clock Stretching for 10-Bit Slave Receive Mode (SEN = 1)

In 10-Bit Slave Receive mode, during the address sequence, clock stretching automatically takes place but CKP is not cleared. During this time, if the UA bit is set after the ninth clock, clock stretching is initiated. The UA bit is set after receiving the upper byte of the 10-bit address, and following the receive of the second byte of the 10-bit address, with the R/W bit cleared to '0'. The release of the clock line occurs upon updating SSPxADD. Clock stretching will occur on each data receive sequence as described in 7-bit mode.

**Note:** If the user polls the UA bit and clears it by updating the SSPxADD register before the falling edge of the ninth clock occurs, and if the user hasn't cleared the BF bit by reading the SSPxBUF register before that time, then the CKP bit will still NOT be asserted low. Clock stretching, on the basis of the state of the BF bit, only occurs during a data sequence, not an address sequence.

### 20.5.7.3 Clock Stretching for 7-Bit Slave Transmit Mode

The 7-Bit Slave Transmit mode implements clock stretching by clearing the CKP bit after the falling edge of the ninth clock if the BF bit is clear. This occurs regardless of the state of the SEN bit.

The user's ISR must set the CKP bit before transmission is allowed to continue. By holding the SCLx line low, the user has time to service the ISR and load the contents of the SSPxBUF before the master device can initiate another transmit sequence (see Figure 20-10).

- Note 1: If the user loads the contents of SSPxBUF, setting the BF bit before the falling edge of the ninth clock, the CKP bit will not be cleared and clock stretching will not occur.
  - **2:** The CKP bit can be set in software, regardless of the state of the BF bit.

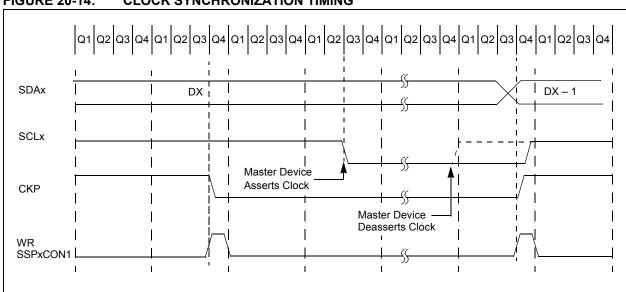

### 20.5.7.4 Clock Stretching for 10-Bit Slave Transmit Mode

In 10-Bit Slave Transmit mode, clock stretching is controlled during the first two address sequences by the state of the UA bit, just as it is in 10-Bit Slave Receive mode. The first two addresses are followed by a third address sequence, which contains the highorder bits of the 10-bit address and the R/W bit set to '1'. After the third address sequence is performed, the UA bit is not set, the module is now configured in Transmit mode and clock stretching is controlled by the BF flag as in 7-Bit Slave Transmit mode (see Figure 20-13).

### 20.5.7.5 Clock Synchronization and the CKP bit

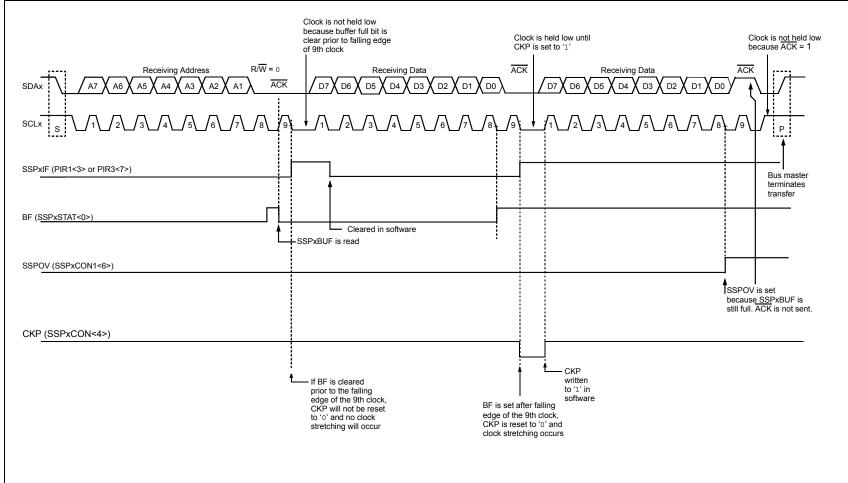

When the CKP bit is cleared, the SCLx output is forced to '0'. However, clearing the CKP bit will not assert the SCLx output low until the SCLx output is already sampled low. Therefore, the CKP bit will not assert the

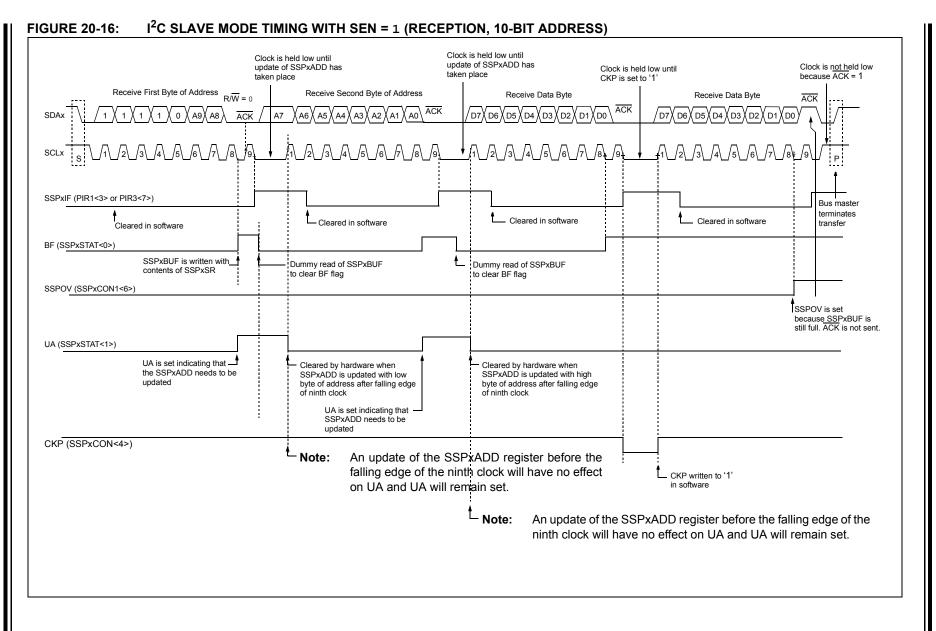

SCLx line until an external I<sup>2</sup>C master device has already asserted the SCLx line. The SCLx output will remain low until the CKP bit is set and all other devices on the I<sup>2</sup>C bus have deasserted SCLx. This ensures that a write to the CKP bit will not violate the minimum high time requirement for SCLx (see Figure 20-14).

**FIGURE 20-14: CLOCK SYNCHRONIZATION TIMING** 

### 20.5.8 GENERAL CALL ADDRESS SUPPORT

The addressing procedure for the I<sup>2</sup>C bus is such that the first byte after the Start condition usually determines which device will be the slave addressed by the master. The exception is the general call address which can address all devices. When this address is used, all devices should, in theory, respond with an Acknowledge.

The general call address is one of eight addresses reserved for specific purposes by the I<sup>2</sup>C protocol. It consists of all '0's with R/W = 0.

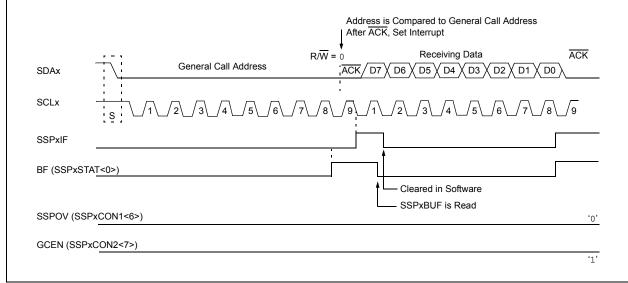

The general call address is recognized when the General Call Enable bit, GCEN, is enabled (SSPx-CON2<7> set). Following a Start bit detect, eight bits are shifted into the SSPxSR and the address is compared against the SSPxADD. It is also compared to the general call address and fixed in hardware.

If the general call address matches, the SSPxSR is transferred to the SSPxBUF, the BF flag bit is set (eighth bit), and on the falling edge of the ninth bit (ACK bit), the SSPxIF interrupt flag bit is set.

When the interrupt is serviced, the source for the interrupt can be checked by reading the contents of the SSPxBUF. The value can be used to determine if the address was device-specific or a general call address.

In 10-Bit Addressing mode, the SSPxADD is required to be updated for the second half of the address to match and the UA bit is set (SSPxSTAT<1>). If the general call address is sampled when the GCEN bit is set, while the slave is configured in 10-Bit Addressing mode, then the second half of the address is not necessary, the UA bit will not be set and the slave will begin receiving data after the Acknowledge (Figure 20-17).

### 20.5.9 MASTER MODE

Master mode is enabled by setting and clearing the appropriate SSPMx bits in SSPxCON1, and by setting the SSPEN bit. In Master mode, the SCLx and SDAx lines are manipulated by the MSSPx hardware if the TRIS bits are set.

The Master mode of operation is supported by interrupt generation on the detection of the Start and Stop conditions. The Stop (P) and Start (S) bits are cleared from a Reset or when the MSSPx module is disabled. Control of the  $I^2C$  bus may be taken when the P bit is set, or the bus is Idle, with both the S and P bits clear.

In Firmware Controlled Master mode, user code conducts all  $I^2C$  bus operations based on Start and Stop bit conditions.

Once Master mode is enabled, the user has six options.

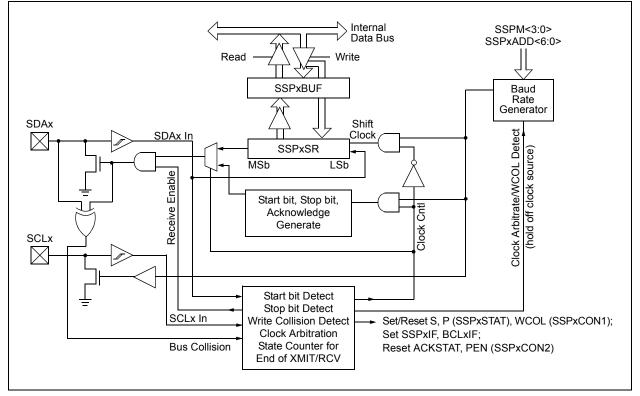

- 1. Assert a Start condition on SDAx and SCLx.
- 2. Assert a Repeated Start condition on SDAx and SCLx.
- 3. Write to the SSPxBUF register initiating transmission of data/address.
- 4. Configure the I<sup>2</sup>C port to receive data.

- 5. Generate an Acknowledge condition at the end of a received byte of data.
- 6. Generate a Stop condition on SDAx and SCLx.
- Note: The MSSPx module, when configured in I<sup>2</sup>C Master mode, does not allow queueing of events. For instance, the user is not allowed to initiate a Start condition and immediately write the SSPxBUF register to initiate transmission before the Start condition is complete. In this case, the SSPxBUF will not be written to and the WCOL bit will be set, indicating that a write to the SSPxBUF did not occur.

The following events will cause the MSSPx Interrupt Flag bit, SSPxIF, to be set (and MSSPx interrupt if enabled):

- Start condition
- Stop condition
- Data transfer byte transmitted/received
- · Acknowledge transmitted
- Repeated Start

### FIGURE 20-18: MSSPx BLOCK DIAGRAM (I<sup>2</sup>C MASTER MODE)

### 20.5.9.1 I<sup>2</sup>C Master Mode Operation

The master device generates all of the serial clock pulses and the Start and Stop conditions. A transfer is ended with a Stop condition or with a Repeated Start condition. Since the Repeated Start condition is also the beginning of the next serial transfer, the I<sup>2</sup>C bus will not be released.

In Master Transmitter mode, serial data is output through SDAx while SCLx outputs the serial clock. The first byte transmitted contains the slave address of the receiving device (7 bits) and the Read/Write (R/W) bit. In this case, the R/W bit will be logic '0'. Serial data is transmitted, 8 bits at a time. After each byte is transmitted, an Acknowledge bit is received. Start and Stop conditions are output to indicate the beginning and the end of a serial transfer.

In Master Receive mode, the first byte transmitted contains the slave address of the transmitting device (7 bits) and the  $R/\overline{W}$  bit. In this case, the  $R/\overline{W}$  bit will be logic '1'. Thus, the first byte transmitted is a 7-bit slave address, followed by a '1' to indicate the receive bit. Serial data is received via SDAx, while SCLx outputs the serial clock. Serial data is received, 8 bits at a time. After each byte is received, an Acknowledge bit is transmitted. Start and Stop conditions indicate the beginning and end of transmission.

The Baud Rate Generator, used for the SPI mode operation, is used to set the SCLx clock frequency for either 100 kHz, 400 kHz or 1 MHz  $I^2C$  operation. See **Section 20.5.10 "Baud Rate**" for more details.

A typical transmit sequence would go as follows:

- 1. The user generates a Start condition by setting the Start Enable bit, SEN (SSPxCON2<0>).
- 2. SSPxIF is set. The MSSPx module will wait the required start time before any other operation takes place.
- 3. The user loads the SSPxBUF with the slave address to transmit.
- 4. Address is shifted out the SDAx pin until all 8 bits are transmitted.
- 5. The MSSPx module shifts in the ACK bit from the slave device and writes its value into the SSPxCON2 register (SSPxCON2<6>).
- The MSSPx module generates an interrupt at the end of the ninth clock cycle by setting the SSPxIF bit.
- 7. The user loads the SSPxBUF with eight bits of data.
- 8. Data is shifted out the SDAx pin until all 8 bits are transmitted.
- The MSSPx module shifts in the ACK bit from the slave device and writes its value into the SSPxCON2 register (SSPxCON2<6>).
- 10. The MSSPx module generates an interrupt at the end of the ninth clock cycle by setting the SSPxIF bit.
- 11. The user generates a Stop condition by setting the Stop Enable bit, PEN (SSPxCON2<2>).
- 12. Interrupt is generated once the Stop condition is complete.

### 20.5.10 BAUD RATE

In I<sup>2</sup>C Master mode, the Baud Rate Generator (BRG) reload value is placed in the lower 7 bits of the SSPxADD register (Figure 20-19). When a write occurs to SSPxBUF, the Baud Rate Generator will automatically begin counting. The BRG counts down to 0 and stops until another reload has taken place. The BRG count is decremented, twice per instruction cycle (TcY), on the Q2 and Q4 clocks. In I<sup>2</sup>C Master mode, the BRG is reloaded automatically.

Once the given operation is complete (i.e., transmission of the last data bit is followed by ACK), the internal clock will automatically stop counting and the SCLx pin will remain in its last state.

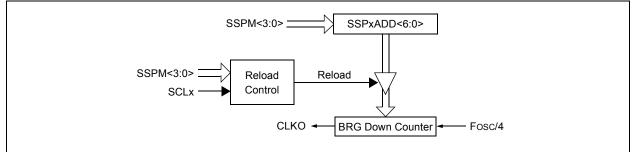

Table 20-2 demonstrates clock rates based on instruction cycles and the BRG value loaded into SSPxADD. The SSPxADD BRG value of  $(0 \times 0.0)$  is not supported.

### 20.5.10.1 Baud Rate and Module Interdependence

Because MSSP1 and MSSP2 are independent, they can operate simultaneously in  $I^2C$  Master mode at different baud rates. This is done by using different BRG reload values for each module.

Because this mode derives its basic clock source from the system clock, any changes to the clock will affect both modules in the same proportion. It may be possible to change one or both baud rates back to a previous value by changing the BRG reload value.

### FIGURE 20-19: BAUD RATE GENERATOR BLOCK DIAGRAM

Fosc	Fcy	Fcy * 2	BRG Value	FscL (2 Rollovers of BRG)
64 MHz	16 MHz	32 MHz	27h	400 kHz <sup>(1)</sup>
64 MHz	16 MHz	32 MHz	32h	313.72 kHz
64 MHz	16 MHz	32 MHz	9Fh	100 kHz
16 MHz	4 MHz	8 MHz	09h	400 kHz <sup>(1)</sup>
16 MHz	4 MHz	8 MHz	0Ch	308 kHz
16 MHz	4 MHz	8 MHz	27h	100 kHz
4 MHz	1 MHz	2 MHz	02h	333 kHz <sup>(1)</sup>
4 MHz	1 MHz	2 MHz	09h	100 kHz
16 MHz	4 MHz	8 MHz	03h	1 MHz <sup>(1,1)</sup>

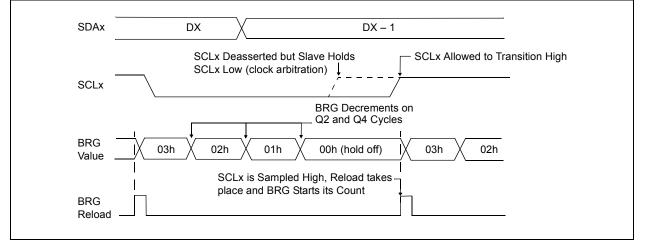

**Note 1:** A minimum of 16 MHz FOSC is required to get 1 MHz  $I^2C$ .

### 20.5.10.2 Clock Arbitration

Clock arbitration occurs when the master, during any receive, transmit or Repeated Start/Stop condition, deasserts the SCLx pin (SCLx allowed to float high). When the SCLx pin is allowed to float high, the Baud Rate Generator (BRG) is suspended from counting until the SCLx pin is actually sampled high. When the

SCLx pin is sampled high, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and begins counting. This ensures that the SCLx high time will always be at least one BRG rollover count in the event that the clock is held low by an external device (Figure 20-20).

### 20.5.11 I<sup>2</sup>C MASTER MODE START CONDITION TIMING

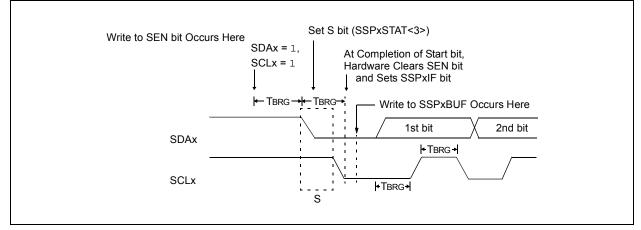

To initiate a Start condition, the user sets the Start Enable bit, SEN (SSPxCON2<0>). If the SDAx and SCLx pins are sampled high, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and starts its count. If SCLx and SDAx are both sampled high when the Baud Rate Generator times out (TBRG), the SDAx pin is driven low. The action of the SDAx being driven low while SCLx is high is the Start condition and causes the S bit (SSPxSTAT<3>) to be set. Following this, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and resumes its count. When the Baud Rate Generator times out (TBRG), the SEN bit (SSPxCON2<0>) will be automatically cleared by hardware. The Baud Rate Generator is suspended, leaving the SDAx line held low and the Start condition is complete.

Note: If, at the beginning of the Start condition, the SDAx and SCLx pins are already sampled low, or if during the Start condition, the SCLx line is sampled low before the SDAx line is driven low, a bus collision occurs, the Bus Collision Interrupt Flag, BCLxIF, is set, the Start condition is aborted and the I<sup>2</sup>C module is reset into its Idle state.

### 20.5.11.1 WCOL Status Flag

If the user writes the SSPxBUF when a Start sequence is in progress, the WCOL bit is set and the contents of the buffer are unchanged (the write doesn't occur).

Note: Because queueing of events is not allowed, writing to the lower 5 bits of SSPxCON2 is disabled until the Start condition is complete.

### FIGURE 20-21: FIRST START BIT TIMING

### 20.5.12 I<sup>2</sup>C MASTER MODE REPEATED START CONDITION TIMING

A Repeated Start condition occurs when the RSEN bit (SSPxCON2<1>) is programmed high and the I<sup>2</sup>C logic module is in the Idle state. When the RSEN bit is set, the SCLx pin is asserted low. When the SCLx pin is sampled low, the Baud Rate Generator is loaded with the contents of SSPxADD<5:0> and begins counting. The SDAx pin is released (brought high) for one Baud Rate Generator count (TBRG). When the Baud Rate Generator times out, and if SDAx is sampled high, the SCLx pin will be deasserted (brought high). When SCLx is sampled high, the Baud Rate Generator is reloaded with the contents of SSPxADD<6:0> and begins counting. SDAx and SCLx must be sampled high for one TBRG. This action is then followed by assertion of the SDAx pin (SDAx = 0) for one TBRG while SCLx is high. Following this, the RSEN bit (SSPx-CON2<1>) will be automatically cleared and the Baud Rate Generator will not be reloaded, leaving the SDAx pin held low. As soon as a Start condition is detected on the SDAx and SCLx pins, the S bit (SSPxSTAT<3>) will be set. The SSPxIF bit will not be set until the Baud Rate Generator has timed out.

- **Note 1:** If RSEN is programmed while any other event is in progress, it will not take effect.
  - **2:** A bus collision during the Repeated Start condition occurs if:
    - •SDAx is sampled low when SCLx goes from low-to-high.

•SCLx goes low before SDAx is asserted low. This may indicate that another master is attempting to transmit a data '1'.

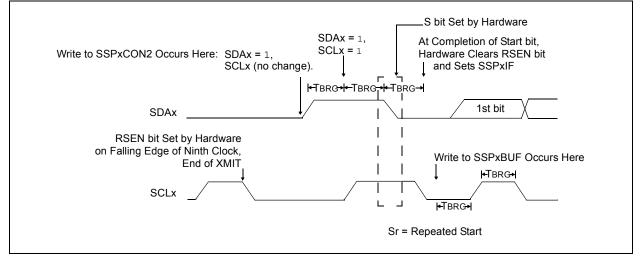

Immediately following the SSPxIF bit getting set, the user may write the SSPxBUF with the 7-bit address in 7-bit mode or the default first address in 10-bit mode. After the first eight bits are transmitted and an ACK is received, the user may then transmit an additional eight bits of address (10-bit mode) or eight bits of data (7-bit mode).

### 20.5.12.1 WCOL Status Flag

If the user writes the SSPxBUF when a Repeated Start sequence is in progress, the WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

Note: Because queueing of events is not allowed, writing of the lower 5 bits of SSPxCON2 is disabled until the Repeated Start condition is complete.

### FIGURE 20-22: REPEATED START CONDITION WAVEFORM

### 20.5.13 I<sup>2</sup>C MASTER MODE TRANSMISSION

Transmission of a data byte, a 7-bit address or the other half of a 10-bit address, is accomplished by simply writing a value to the SSPxBUF register. This action will set the Buffer Full flag bit, BF, and allow the Baud Rate Generator to begin counting and start the next transmission. Each bit of address/data will be shifted out onto the SDAx pin after the falling edge of SCLx is asserted (see data hold time specification Parameter 106). SCLx is held low for one Baud Rate Generator rollover count (TBRG). Data should be valid before SCLx is released high (see data setup time specification Parameter 107). When the SCLx pin is released high, it is held that way for TBRG. The data on the SDAx pin must remain stable for that duration and some hold time after the next falling edge of SCLx. After the eighth bit is shifted out (the falling edge of the eighth clock), the BF flag is cleared and the master releases SDAx. This allows the slave device being addressed to respond with an ACK bit during the ninth bit time if an address match occurred, or if data was received properly. The status of ACK is written into the ACKDT bit on the falling edge of the ninth clock. If the master receives an Acknowledge, the Acknowledge Status bit, ACKSTAT, is cleared; if not, the bit is set. After the ninth clock, the SSPxIF bit is set and the master clock (Baud Rate Generator) is suspended until the next data byte is loaded into the SSPxBUF, leaving SCLx low and SDAx unchanged (Figure 20-23).

After the write to the SSPxBUF, each bit of the address will be shifted out on the falling edge of SCLx until all seven address bits and the R/W bit are completed. On the falling edge of the eighth clock, the master will deassert the SDAx pin, allowing the slave to respond with an Acknowledge. On the falling edge of the ninth clock, the master will sample the SDAx pin to see if the address was recognized by a slave. The status of the ACK bit is loaded into the ACKSTAT Status bit (SSPxCON2<6>). Following the falling edge of the ninth clock transmission of the address, the SSPxIF flag is set, the BF flag is cleared and the Baud Rate Generator is turned off until another write to the SSPxBUF takes place, holding SCLx low and allowing SDAx to float.

### 20.5.13.1 BF Status Flag

In Transmit mode, the BF bit (SSPxSTAT<0>) is set when the CPU writes to SSPxBUF and is cleared when all 8 bits are shifted out.

### 20.5.13.2 WCOL Status Flag

If the user writes the SSPxBUF when a transmit is already in progress (i.e., SSPxSR is still shifting out a data byte), the WCOL bit is set and the contents of the buffer are unchanged (the write doesn't occur) after 2 TCY after the SSPxBUF write. If SSPxBUF is rewritten within 2 TCY, the WCOL bit is set and SSPxBUF is updated. This may result in a corrupted transfer.

The user should verify that the WCOL bit is clear after each write to SSPxBUF to ensure the transfer is correct. In all cases, WCOL must be cleared in software.

### 20.5.13.3 ACKSTAT Status Flag

In Transmit mode, the ACKSTAT bit (SSPxCON2<6>) is cleared when the slave has sent an Acknowledge  $(\overline{ACK} = 0)$  and is set when the slave does not Acknowledge  $(\overline{ACK} = 1)$ . A slave sends an Acknowledge when it has recognized its address (including a general call), or when the slave has properly received its data.

### 20.5.14 I<sup>2</sup>C MASTER MODE RECEPTION

Master mode reception is enabled by programming the Receive Enable bit, RCEN (SSPxCON2<3>).

Note:	The MSSPx module must be in an inactive
	state before the RCEN bit is set or the
	RCEN bit will be disregarded.

The Baud Rate Generator begins counting, and on each rollover, the state of the SCLx pin changes (highto-low/low-to-high) and data is shifted into the SSPxSR. After the falling edge of the eighth clock, the receive enable flag is automatically cleared, the contents of the SSPxSR are loaded into the SSPxBUF, the BF flag bit is set, the SSPxIF flag bit is set and the Baud Rate Generator is suspended from counting, holding SCLx low. The MSSPx is now in Idle state awaiting the next command. When the buffer is read by the CPU, the BF flag bit is automatically cleared. The user can then send an Acknowledge bit at the end of reception by setting the Acknowledge Sequence Enable bit, ACKEN (SSPxCON2<4>).

### 20.5.14.1 BF Status Flag

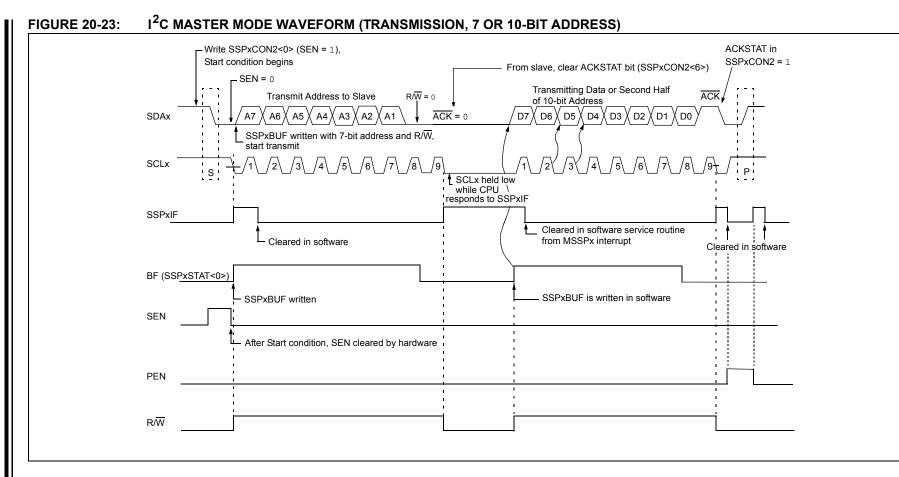

In receive operation, the BF bit is set when an address or data byte is loaded into SSPxBUF from SSPxSR. It is cleared when the SSPxBUF register is read.

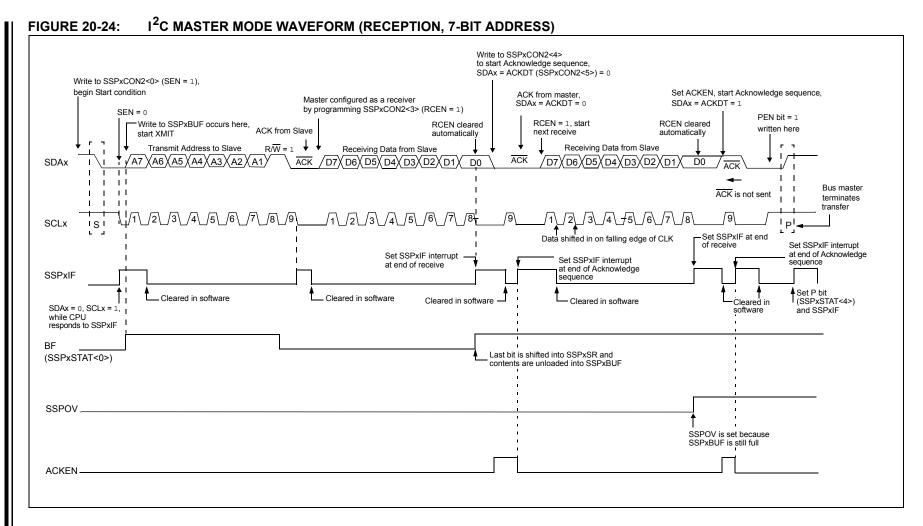

### 20.5.14.2 SSPOV Status Flag

In receive operation, the SSPOV bit is set when 8 bits are received into the SSPxSR and the BF flag bit is already set from a previous reception.

### 20.5.14.3 WCOL Status Flag

If the user writes the SSPxBUF when a receive is already in progress (i.e., SSPxSR is still shifting in a data byte), the WCOL bit is set and the contents of the buffer are unchanged (the write doesn't occur).

#### 20.5.15 ACKNOWLEDGE SEQUENCE TIMING

An Acknowledge sequence is enabled by setting the Acknowledge Sequence Enable bit, ACKEN (SSPx-CON2<4>). When this bit is set, the SCLx pin is pulled low and the contents of the Acknowledge data bit are presented on the SDAx pin. If the user wishes to generate an Acknowledge, then the ACKDT bit should be cleared. If not, the user should set the ACKDT bit before starting an Acknowledge sequence. The Baud Rate Generator then counts for one rollover period (TBRG) and the SCLx pin is deasserted (pulled high). When the SCLx pin is sampled high (clock arbitration), the Baud Rate Generator counts for TBRG; the SCLx pin is then pulled low. Following this, the ACKEN bit is automatically cleared, the Baud Rate Generator is turned off and the MSSPx module then goes into an inactive state (Figure 20-25).

#### 20.5.15.1 WCOL Status Flag

If the user writes the SSPxBUF when an Acknowledge sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

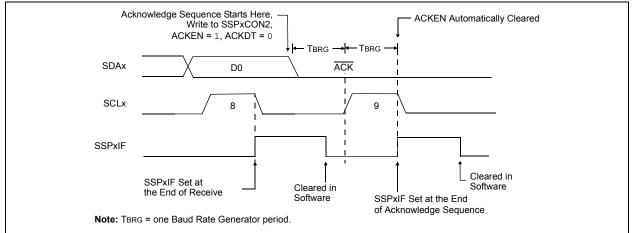

#### 20.5.16 STOP CONDITION TIMING

A Stop bit is asserted on the SDAx pin at the end of a receive/transmit by setting the Stop Sequence Enable bit, PEN (SSPxCON2<2>). At the end of a receive/ transmit, the SCLx line is held low after the falling edge of the ninth clock. When the PEN bit is set, the master will assert the SDAx line low. When the SDAx line is sampled low, the Baud Rate Generator is reloaded and counts down to 0. When the Baud Rate Generator times out, the SCLx pin will be brought high and one TBRG (Baud Rate Generator rollover count) later, the SDAx pin will be deasserted. When the SDAx pin is sampled high while SCLx is high, the P bit (SSPxSTAT<4>) is set. A TBRG later, the PEN bit is cleared and the SSPxIF bit is set (Figure 20-26).

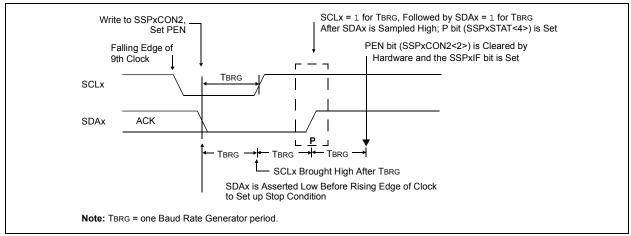

#### 20.5.16.1 WCOL Status Flag

If the user writes the SSPxBUF when a Stop sequence is in progress, then the WCOL bit is set and the contents of the buffer are unchanged (the write doesn't occur).

#### FIGURE 20-25: ACKNOWLEDGE SEQUENCE WAVEFORM

#### FIGURE 20-26: STOP CONDITION RECEIVE OR TRANSMIT MODE

#### 20.5.17 SLEEP OPERATION

While in Sleep mode, the I<sup>2</sup>C module can receive addresses or data and when an address match or complete byte transfer occurs, wake the processor from Sleep (if the MSSPx interrupt is enabled).

#### 20.5.18 EFFECTS OF A RESET

A Reset disables the MSSPx module and terminates the current transfer.

#### 20.5.19 MULTI-MASTER MODE

In Multi-Master mode, the interrupt generation on the detection of the Start and Stop conditions allows the determination of when the bus is free. The Stop (P) and Start (S) bits are cleared from a Reset or when the MSSPx module is disabled. Control of the I<sup>2</sup>C bus may be taken when the P bit (SSPxSTAT<4>) is set, or the bus is Idle, with both the S and P bits clear. When the bus is busy, enabling the MSSPx interrupt will generate the interrupt when the Stop condition occurs.

In multi-master operation, the SDAx line must be monitored for arbitration to see if the signal level is the expected output level. This check is performed in hardware with the result placed in the BCLxIF bit.

The states where arbitration can be lost are:

- · Address Transfer
- Data Transfer
- A Start Condition
- A Repeated Start Condition
- An Acknowledge Condition

#### 20.5.20 MULTI -MASTER COMMUNICATION, BUS COLLISION AND BUS ARBITRATION

Multi-Master mode support is achieved by bus arbitration. When the master outputs address/data bits onto the SDAx pin, arbitration takes place when the master outputs a '1' on SDAx, by letting SDAx float high, and another master asserts a '0'. When the SCLx pin floats high, data should be stable. If the expected data on SDAx is a '1' and the data sampled on the SDAx pin = 0, then a bus collision has taken place. The master will set the Bus Collision Interrupt Flag, BCLxIF, and reset the  $I^2C$  port to its Idle state (Figure 20-27).

If a transmit was in progress when the bus collision occurred, the transmission is halted, the BF flag is cleared, the SDAx and SCLx lines are deasserted and the SSPxBUF can be written to. When the user services the bus collision Interrupt Service Routine and if the I<sup>2</sup>C bus is free, the user can resume communication by asserting a Start condition.

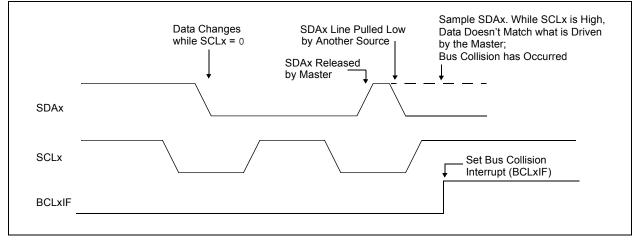

If a Start, Repeated Start, Stop or Acknowledge condition was in progress when the bus collision occurred, the condition is aborted, the SDAx and SCLx lines are deasserted and the respective control bits in the SSPx-CON2 register are cleared. When the user services the bus collision Interrupt Service Routine (ISR), and if the I<sup>2</sup>C bus is free, the user can resume communication by asserting a Start condition.

The master will continue to monitor the SDAx and SCLx pins. If a Stop condition occurs, the SSPxIF bit will be set.

A write to the SSPxBUF will start the transmission of data at the first data bit regardless of where the transmitter left off when the bus collision occurred.

In Multi-Master mode, the interrupt generation on the detection of Start and Stop conditions allows the determination of when the bus is free. Control of the I<sup>2</sup>C bus can be taken when the P bit is set in the SSPxSTAT register, or the bus is Idle and the S and P bits are cleared.

#### 20.5.20.1 Bus Collision During a Start Condition

During a Start condition, a bus collision occurs if:

- a) SDAx or SCLx is sampled low at the beginning of the Start condition (Figure 20-28).
- b) SCLx is sampled low before SDAx is asserted low (Figure 20-29).

During a Start condition, both the SDAx and the SCLx pins are monitored.

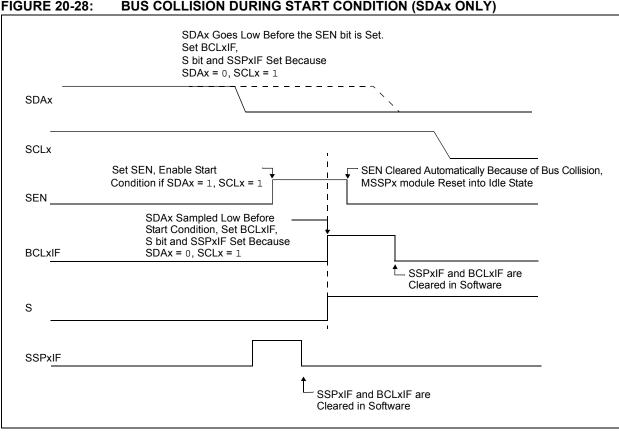

If the SDAx pin is already low, or the SCLx pin is already low, then all of the following occur:

- · the Start condition is aborted,
- · the BCLxIF flag is set and
- · the MSSPx module is reset to its inactive state (Figure 20-28)

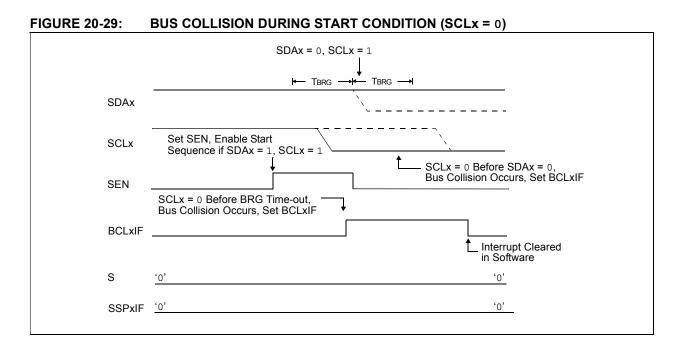

The Start condition begins with the SDAx and SCLx pins deasserted. When the SDAx pin is sampled high, the Baud Rate Generator is loaded from SSPxADD<6:0> and counts down to 0. If the SCLx pin is sampled low while SDAx is high, a bus collision occurs because it is assumed that another master is attempting to drive a data '1' during the Start condition.

If the SDAx pin is sampled low during this count, the BRG is reset and the SDAx line is asserted early (Figure 20-30). If, however, a '1' is sampled on the SDAx pin, the SDAx pin is asserted low at the end of the BRG count. The Baud Rate Generator is then reloaded and counts down to 0. If the SCLx pin is sampled as '0' during this time, a bus collision does not occur. At the end of the BRG count, the SCLx pin is asserted low.

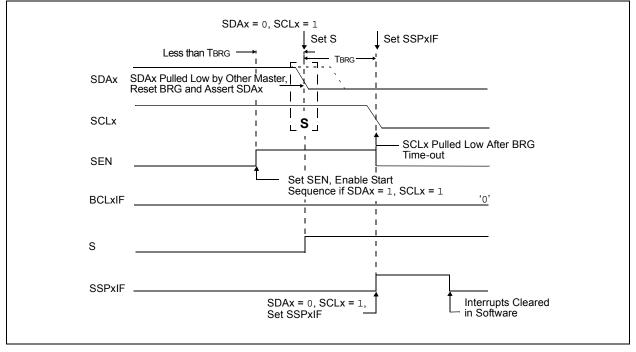

Note: The reason that bus collision is not a factor during a Start condition is that no two bus masters can assert a Start condition at the exact same time. Therefore, one master will always assert SDAx before the other. This condition does not cause a bus collision because the two masters must be allowed to arbitrate the first address following the Start condition. If the address is the same, arbitration must be allowed to continue into the data portion, Repeated Start or Stop conditions.

#### FIGURE 20-28: BUS COLLISION DURING START CONDITION (SDAx ONLY)

### 20.5.20.2 Bus Collision During a Repeated Start Condition

During a Repeated Start condition, a bus collision occurs if:

- a) A low level is sampled on SDAx when SCLx goes from a low level to a high level.
- b) SCLx goes low before SDAx is asserted low, indicating that another master is attempting to transmit a data '1'.

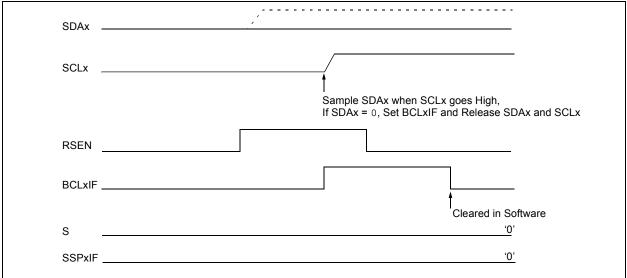

When the user deasserts SDAx and the pin is allowed to float high, the BRG is loaded with SSPxADD<6:0> and counts down to 0. The SCLx pin is then deasserted and when sampled high, the SDAx pin is sampled.

If SDAx is low, a bus collision has occurred (i.e., another master is attempting to transmit a data '0', Figure 20-31). If SDAx is sampled high, the BRG is reloaded and begins counting. If SDAx goes from high-to-low before the BRG times out, no bus collision occurs because no two masters can assert SDAx at exactly the same time.

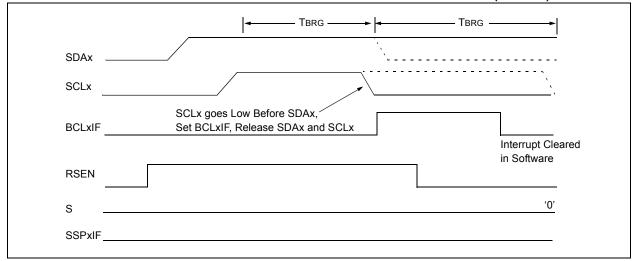

If SCLx goes from high-to-low before the BRG times out and SDAx has not already been asserted, a bus collision occurs. In this case, another master is attempting to transmit a data '1' during the Repeated Start condition (see Figure 20-32).

If, at the end of the BRG time-out, both SCLx and SDAx are still high, the SDAx pin is driven low and the BRG is reloaded and begins counting. At the end of the count, regardless of the status of the SCLx pin, the SCLx pin is driven low and the Repeated Start condition is complete.

#### FIGURE 20-31: BUS COLLISION DURING A REPEATED START CONDITION (CASE 1)

#### FIGURE 20-32: BUS COLLISION DURING REPEATED START CONDITION (CASE 2)

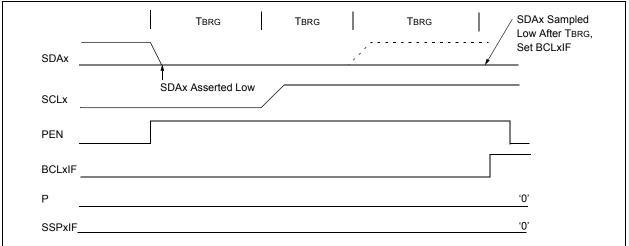

#### 20.5.20.3 Bus Collision During a Stop Condition

Bus collision occurs during a Stop condition if:

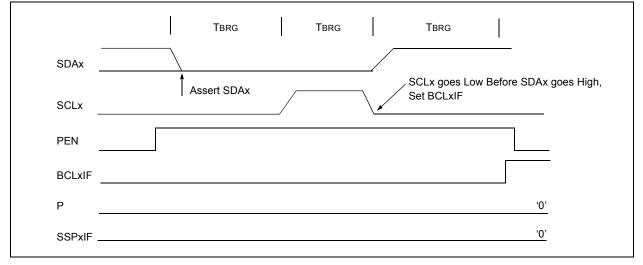

- a) After the SDAx pin has been deasserted and allowed to float high, SDAx is sampled low after the BRG has timed out.
- b) After the SCLx pin is deasserted, SCLx is sampled low before SDAx goes high.

The Stop condition begins with SDAx asserted low. When SDAx is sampled low, the SCLx pin is allowed to float. When the pin is sampled high (clock arbitration), the Baud Rate Generator is loaded with SSPxADD<6:0> and counts down to 0. After the BRG times out, SDAx is sampled. If SDAx is sampled low, a bus collision has occurred. This is due to another master attempting to drive a data '0' (Figure 20-33). If the SCLx pin is sampled low before SDAx is allowed to float high, a bus collision occurs. This is another case of another master attempting to drive a data '0' (Figure 20-34).

### 21.0 ENHANCED UNIVERSAL SYNCHRONOUS ASYNCHRONOUS RECEIVER TRANSMITTER (EUSART)

The Enhanced Universal Synchronous Asynchronous Receiver Transmitter (EUSART) module is one of four serial I/O modules. (Generically, the EUSART is also known as a Serial Communications Interface or SCI.) The EUSART can be configured as a full-duplex, asynchronous system that can communicate with peripheral devices, such as CRT terminals and personal computers. It can also be configured as a halfduplex synchronous system that can communicate with peripheral devices, such as A/D or D/A integrated circuits, serial EEPROMs, etc.

The Enhanced USART module implements additional features, including automatic baud rate detection and calibration, automatic wake-up on Sync Break reception and 12-bit Break character transmit. These make it ideally suited for use in Local Interconnect Network bus (LIN/J2602 bus) systems.

All members of the PIC18FXXJ94 are equipped with four independent EUSART modules, referred to as EUSART1, EUSART2, EUSART3 and EUSART4. They can be configured in the following modes:

- · Asynchronous (full duplex) with:
  - Auto-wake-up on character reception
  - Auto-baud calibration
  - 12-bit Break character transmission
- Synchronous Master (half duplex) with selectable clock polarity
- Synchronous Slave (half duplex) with selectable clock polarity

The Enhanced USART module has the following enhancements over the AUSART module:

- Selectable 16-Bit Baud Rate Generator mode
- Interrupt on Sync Break character received; allows an asynchronous wake-up from Sleep
- · 12-Bit Break character transmit
- · Auto-baud calibration on Sync character
- · Clock polarity select for Synchronous mode
- Transmit and receive polarity select for Asynchronous mode
- · Receive Shift register empty Status bit
- Local Interconnect Network (LIN/J2602) protocol standard

The Enhanced USART module has the following IrDA<sup>®</sup> related enhancements over previous Enhanced USART modules:

- 16x Baud Clock output for IrDA support
- IrDA encoder and decoder logic

The pins of EUSART1 through EUSART4 are multiplexed with functions using PPS-Lite. The TXx and RXx pins of each EUSART can be individually controlled using PPS-Lite registers, respectively.

Refer to **Section 11.15 "PPS-Lite**" for setting up EUSART1 through EUSART4.

**Note:** The EUSART control will automatically reconfigure the pin from input to output as needed.

The operation of each Enhanced USART module is controlled through seven registers:

- RCSTAx EUSARTx Receive Status and Control Register
- TXSTAx EUSARTx Transmit Status and Control Register
- · BAUDCONx Baud Rate Control Register
- SPBRGx Baud Rate Generator Register
- SPBRGHx Baud Rate Generator High Register
- RCREGx EUSARTx Receive Data Register
- TXREGx EUSARTx Transmit Data Register

These are detailed on the following pages in Register 21-1, Register 21-2 and Register 21-3, respectively.

Note: Throughout this section, references to register and bit names that may be associated with a specific EUSART module are referred to generically by the use of 'x' in place of the specific module number. Thus, "RCSTAx" might refer to the Receive STATUS register for either EUSART1, EUSART2, EUSART3 or EUSART4.

Note 1: Th		nly available in A	synchronous r	node with the 16	ax clock prese	t The 16x clock	is procent f

**Note 1:** This feature is only available in Asynchronous mode with the 16x clock preset. The 16x clock is present for both the x16 and x64 BRG configurations.

#### bit 0 ABDEN: Auto-Baud Detect Enable bit

Asynchronous mode:

- 1 = Enables baud rate measurement on the next character, requires reception of a Sync field (55h); cleared in hardware upon completion
- 0 = Baud rate measurement is disabled or has completed

Synchronous mode:

Unused in this mode.

**Note 1:** This feature is only available in Asynchronous mode with the 16x clock preset. The 16x clock is present for both the x16 and x64 BRG configurations.

#### 21.1 Baud Rate Generator (BRG)

The BRG is a dedicated, 8-bit or 16-bit generator that supports both the Asynchronous and Synchronous modes of the EUSARTx. By default, the BRG operates in 8-bit mode; setting the BRG16 bit (BAUDCONx<3>) selects 16-bit mode.

The SPBRGHx:SPBRGx register pair controls the period of a free-running timer. In Asynchronous mode, bits, BRGH (TXSTAx<2>) and BRG16 (BAUDCONx<3>), also control the baud rate. In Synchronous mode, BRGH is ignored. Table 21-1 shows the formula for computation of the baud rate for different EUSARTx modes which only apply in Master mode (internally generated clock).

Given the desired baud rate and FOSC, the nearest integer value for the SPBRGHx:SPBRGx registers can be calculated using the formulas in Table 21-1. From this, the error in baud rate can be determined. An example calculation is shown in Example 21-1. Typical baud rates and error values for the various Asynchronous modes are shown in Table 21-2. It may be advantageous to use

the high baud rate (BRGH = 1) or the 16-bit BRG to reduce the baud rate error, or achieve a slow baud rate for a fast oscillator frequency.

Writing a new value to the SPBRGHx:SPBRGx registers causes the BRG timer to be reset (or cleared). This ensures the BRG does not wait for a timer overflow before outputting the new baud rate. When operated in the Synchronous mode, SPBRGH:SPBRG values of 0000h and 0001h are not supported. In the Asynchronous mode, all BRG values may be used.

#### 21.1.1 OPERATION IN POWER-MANAGED MODES

The device clock is used to generate the desired baud rate. When one of the power-managed modes is entered, the new clock source may be operating at a different frequency. This may require an adjustment to the value in the SPBRGx register pair.

#### 21.1.2 SAMPLING

The data on the RXx pin is sampled three times by a majority detect circuit to determine if a high or a low level is present at the RXx pin.

C	onfiguration B	its	BRG/EUSART Mode	Baud Rate Formula		
SYNC	BRG16	BRGH	BRG/EUSART Mode			
0	0	0	8-bit/Asynchronous	Fosc/[64 (n + 1)]		
0	0	1	8-bit/Asynchronous			
0	1	0	16-bit/Asynchronous	Fosc/[16 (n + 1)]		
0	1	1	16-bit/Asynchronous			
1	0	x	8-bit/Synchronous	Fosc/[4 (n + 1)]		
1	1 1 x		16-bit/Synchronous	1		

#### TABLE 21-1: BAUD RATE FORMULAS

**Legend:** x = Don't care, n = value of SPBRGHx:SPBRGx register pair

#### EXAMPLE 21-1: CALCULATING BAUD RATE ERROR

For a device with Fosc of 16 MHz, des	red baud rate of 9600, Asynchronous mode, and 8-bit BRG:
Desired Baud Rate = Fosc/(6	64 ([SPBRGHx:SPBRGx] + 1))
Solving for SPBRGHx:SPBRGx:	
X = ((Fosc/	Desired Baud Rate)/64) – 1
= ((16000	000/9600)/64) – 1
= [25.042	] = 25
Calculated Baud Rate = 160000	00/(64 (25 + 1))
= 9615	
Error = (Calcul	ated Baud Rate – Desired Baud Rate)/Desired Baud Rate
= (9615 -	· 9600)/9600 = 0.16%

#### 21.1.3 AUTO-BAUD RATE DETECT

The Enhanced USART module supports the automatic detection and calibration of baud rate. This feature is active only in Asynchronous mode and while the WUE bit is clear.

The automatic baud rate measurement sequence (Figure 21-1) begins whenever a Start bit is received and the ABDEN bit is set. The calculation is self-averaging.

In the Auto-Baud Rate Detect (ABD) mode, the clock to the BRG is reversed. Rather than the BRG clocking the incoming RXx signal, the RXx signal is timing the BRG. In ABD mode, the internal Baud Rate Generator is used as a counter to time the bit period of the incoming serial byte stream.

Once the ABDEN bit is set, the state machine will clear the BRG and look for a Start bit. The Auto-Baud Rate Detect must receive a byte with the value, 55h (ASCII "U", which is also the LIN/J2602 bus Sync character), in order to calculate the proper bit rate. The measurement is taken over both a low and a high bit time in order to minimize any effects caused by asymmetry of the incoming signal. After a Start bit, the SPBRGx begins counting up, using the preselected clock source on the first rising edge of RXx. After eight bits on the RXx pin or the fifth rising edge, an accumulated value totalling the proper BRG period is left in the SPBRGHx:SPBRGx register pair. Once the 5th edge is seen (this should correspond to the Stop bit), the ABDEN bit is automatically cleared.

If a rollover of the BRG occurs (an overflow from FFFFh to 0000h), the event is trapped by the ABDOVF Status bit (BAUDCONx<7>). It is set in hardware by BRG rollovers and can be set or cleared by the user in software. ABD mode remains active after rollover events and the ABDEN bit remains set (Figure 21-2).

While calibrating the baud rate period, the BRG registers are clocked at 1/8th the preconfigured clock rate. The BRG clock will be configured by the BRG16 and BRGH bits. The BRG16 bit must be set to use both SPBRG1 and SPBRGH1 as a 16-bit counter. This allows the user to verify that no carry occurred for 8-bit modes by checking for 00h in the SPBRGHx register. Refer to Table 21-3 for counter clock rates to the BRG.

While the ABD sequence takes place, the EUSARTx state machine is held in Idle. The RCxIF interrupt is set once the fifth rising edge on RXx is detected. The value in the RCREGx needs to be read to clear the RCxIF interrupt. The contents of RCREGx should be discarded.

- Note 1: If the WUE bit is set with the ABDEN bit, Auto-Baud Rate Detection will occur on the byte *following* the Break character.
  - 2: It is up to the user to determine that the incoming character baud rate is within the range of the selected BRG clock source. Some combinations of oscillator frequency and EUSARTx baud rates are not possible due to bit error rates. Overall system timing and communication baud rates must be taken into consideration when using the Auto-Baud Rate Detection feature.
  - **3:** To maximize baud rate range, if that feature is used it is recommended that the BRG16 bit (BAUDCONx<3>) be set.

### TABLE 21-3:BRG COUNTERCLOCK RATES

BRG16	BRGH	BRG Counter Clock
0	0	Fosc/512
0	1	Fosc/128
1	0	Fosc/128
1	1	Fosc/32

#### 21.1.3.1 ABD and EUSARTx Transmission

Since the BRG clock is reversed during ABD acquisition, the EUSARTx transmitter cannot be used during ABD. This means that whenever the ABDEN bit is set, TXREGx cannot be written to. Users should also ensure that ABDEN does not become set during a transmit sequence. Failing to do this may result in unpredictable EUSARTx operation.

			1

#### 21.2 EUSARTx Asynchronous Mode

The Asynchronous mode of operation is selected by clearing the SYNC bit (TXSTAx<4>). In this mode, the EUSARTx uses standard Non-Return-to-Zero (NRZ) format (one Start bit, eight or nine data bits and one Stop bit). The most common data format is 8 bits. An on-chip, dedicated 8-bit/16-bit Baud Rate Generator can be used to derive standard baud rate frequencies from the oscillator.

The EUSARTx transmits and receives the LSb first. The EUSARTx's transmitter and receiver are functionally independent but use the same data format and baud rate. The Baud Rate Generator produces a clock, either x16 or x64 of the bit shift rate, depending on the BRGH and BRG16 bits (TXSTAx<2> and BAUDCONx<3>). Parity is not supported by the hardware but can be implemented in software and stored as the 9th data bit.

When operating in Asynchronous mode, the EUSARTx module consists of the following important elements:

- · Baud Rate Generator
- · Sampling Circuit
- Asynchronous Transmitter
- · Asynchronous Receiver
- Auto-Wake-up on Sync Break Character
- 12-Bit Break Character Transmit
- Auto-Baud Rate Detection

#### 21.2.1 EUSARTx ASYNCHRONOUS TRANSMITTER

The EUSARTx transmitter block diagram is shown in Figure 21-3. The heart of the transmitter is the Transmit (Serial) Shift Register (TSR). The Shift register obtains its data from the Read/Write Transmit Buffer register, TXREGx. The TXREGx register is loaded with data in software. The TSR register is not loaded until the Stop bit has been transmitted from the previous load. As soon as the Stop bit is transmitted, the TSR is loaded with new data from the TXREGx register (if available).

Once the TXREGx register transfers the data to the TSR register (occurs in one TCY), the TXREGx register is empty and the TXxIF flag bit is set. This interrupt can be enabled or disabled by setting or clearing the interrupt enable bit, TXxIE. TXxIF will be set regardless of the state of TXxIE; it cannot be cleared in software. TXxIF is also not cleared immediately upon loading TXREGx, but becomes valid in the second instruction cycle following the load instruction. Polling TXxIF immediately following a load of TXREGx will return invalid results.

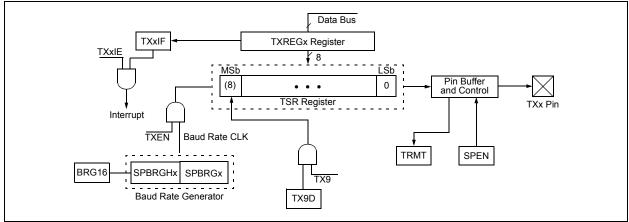

While TXxIF indicates the status of the TXREGx register, another bit, TRMT (TXSTAx<1>), shows the status of the TSR register. TRMT is a read-only bit which is set when the TSR register is empty. No interrupt logic is tied to this bit so the user has to poll this bit in order to determine if the TSR register is empty.

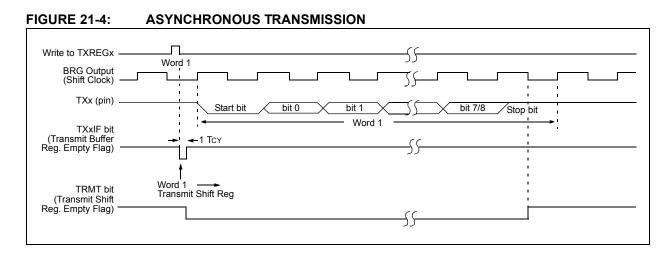

Note 1:	The TSR register is not mapped in data memory, so it is not available to the user.
2:	Flag bit, TXxIF, is set when enable bit, TXEN, is set.

To set up an Asynchronous Transmission:

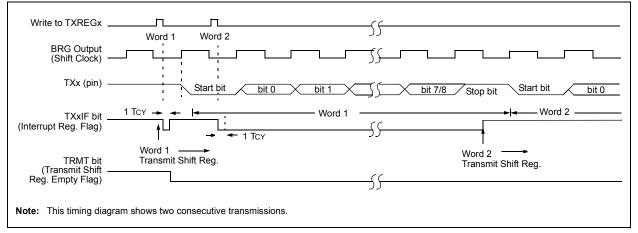

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing bit, SYNC, and setting bit, SPEN.
- 3. If interrupts are desired, set enable bit, TXxIE.
- 4. If 9-bit transmission is desired, set transmit bit, TX9. Can be used as address/data bit.
- 5. Enable the transmission by setting bit, TXEN, which will also set bit, TXxIF.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit, TX9D.
- 7. Load data to the TXREGx register (starts transmission).
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### FIGURE 21-3: EUSARTX TRANSMIT BLOCK DIAGRAM

#### FIGURE 21-5: ASYNCHRONOUS TRANSMISSION (BACK-TO-BACK)

#### 21.2.2 EUSARTx ASYNCHRONOUS RECEIVER

The receiver block diagram is shown in Figure 21-6. The data is received on the RXx pin and drives the data recovery block. The data recovery block is actually a high-speed shifter operating at x16 times the baud rate, whereas the main receive serial shifter operates at the bit rate or at Fosc. This mode would typically be used in RS-232 systems.

To set up an Asynchronous Reception:

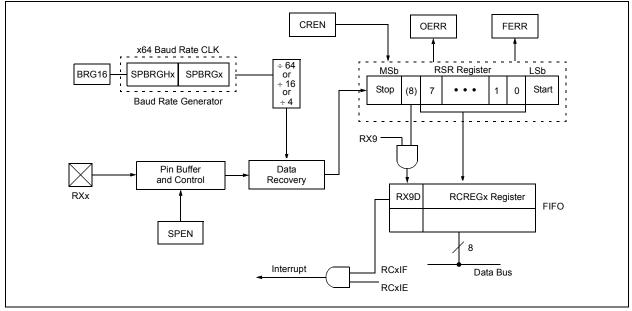

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing bit, SYNC, and setting bit, SPEN.
- 3. If interrupts are desired, set enable bit, RCxIE.
- 4. If 9-bit reception is desired, set bit, RX9.
- 5. Enable the reception by setting bit, CREN.
- Flag bit, RCxIF, will be set when reception is complete and an interrupt will be generated if enable bit, RCxIE, was set.
- 7. Read the RCSTAx register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 8. Read the 8-bit received data by reading the RCREGx register.
- 9. If any error occurred, clear the error by clearing enable bit, CREN.
- 10. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### 21.2.3 SETTING UP 9-BIT MODE WITH ADDRESS DETECT

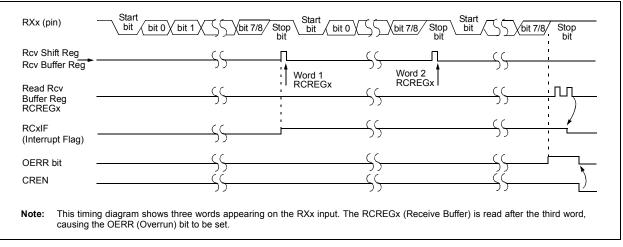

This mode would typically be used in RS-485 systems. To set up an Asynchronous Reception with Address Detect Enable:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRGH and BRG16 bits, as required, to achieve the desired baud rate.
- 2. Enable the asynchronous serial port by clearing the SYNC bit and setting the SPEN bit.
- 3. If interrupts are required, set the RCEN bit and select the desired priority level with the RCxIP bit.
- 4. Set the RX9 bit to enable 9-bit reception.
- 5. Set the ADDEN bit to enable address detect.
- 6. Enable reception by setting the CREN bit.
- The RCxIF bit will be set when reception is complete. The interrupt will be Acknowledged if the RCxIE and GIE bits are set.
- 8. Read the RCSTAx register to determine if any error occurred during reception, as well as read bit 9 of data (if applicable).
- 9. Read RCREGx to determine if the device is being addressed.
- 10. If any error occurred, clear the CREN bit.
- 11. If the device has been addressed, clear the ADDEN bit to allow all received data into the receive buffer and interrupt the CPU.

#### FIGURE 21-7: ASYNCHRONOUS RECEPTION

#### 21.2.4 AUTO-WAKE-UP ON SYNC BREAK CHARACTER

During Sleep mode, all clocks to the EUSARTx are suspended. Because of this, the Baud Rate Generator is inactive and a proper byte reception cannot be performed. The auto-wake-up feature allows the controller to wake-up due to activity on the RXx/DTx line while the EUSARTx is operating in Asynchronous mode.

The auto-wake-up feature is enabled by setting the WUE bit (BAUDCONx<1>). Once set, the typical receive sequence on RXx/DTx is disabled and the EUSARTx remains in an Idle state, monitoring for a wake-up event independent of the CPU mode. A wake-up event consists of a high-to-low transition on the RXx/DTx line. (This coincides with the start of a Sync Break or a Wake-up Signal character for the LIN/J2602 protocol.)

Following a wake-up event, the module generates an RCxIF interrupt. The interrupt is generated synchronously to the Q clocks in normal operating modes (Figure 21-8) and asynchronously if the device is in Sleep mode (Figure 21-9). The interrupt condition is cleared by reading the RCREGx register.

The WUE bit is automatically cleared once a low-to-high transition is observed on the RXx line following the wake-up event. At this point, the EUSARTx module is in Idle mode and returns to normal operation. This signals to the user that the Sync Break event is over.

### 21.2.4.1 Special Considerations Using Auto-Wake-up

Since auto-wake-up functions by sensing rising edge transitions on RXx/DTx, information with any state changes before the Stop bit may signal a false End-of-Character (EOC) and cause data or framing errors. To work properly, therefore, the initial character in the transmission must be all '0's. This can be 00h (8 bits) for standard RS-232 devices or 000h (12 bits) for the LIN/J2602 bus.

Oscillator start-up time must also be considered, especially in applications using oscillators with longer start-up intervals (i.e., HS or HSPLL mode). The Sync Break (or Wake-up Signal) character must be of sufficient length and be followed by a sufficient interval to allow enough time for the selected oscillator to start and provide proper initialization of the EUSARTx.

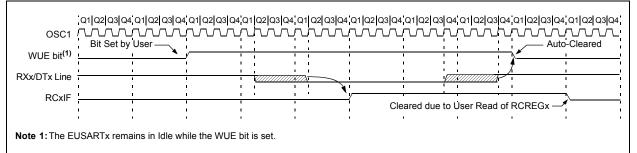

### 21.2.4.2 Special Considerations Using the WUE Bit

The timing of WUE and RCxIF events may cause some confusion when it comes to determining the validity of received data. As noted, setting the WUE bit places the EUSARTx in an Idle mode. The wake-up event causes a receive interrupt by setting the RCxIF bit. The WUE bit is cleared after this when a rising edge is seen on RXx/DTx. The interrupt condition is then cleared by reading the RCREGx register. Ordinarily, the data in RCREGx will be dummy data and should be discarded.

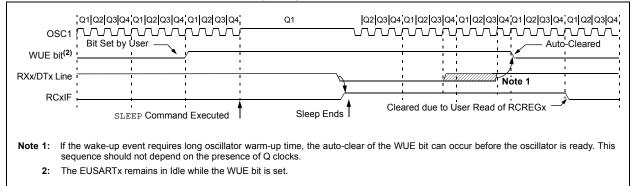

The fact that the WUE bit has been cleared (or is still set), and the RCxIF flag is set, should not be used as an indicator of the integrity of the data in RCREGx. Users should consider implementing a parallel method in firmware to verify received data integrity.

To assure that no actual data is lost, check the RCIDL bit to verify that a receive operation is not in process. If a receive operation is not occurring, the WUE bit may then be set just prior to entering the Sleep mode.

#### FIGURE 21-8: AUTO-WAKE-UP BIT (WUE) TIMINGS DURING NORMAL OPERATION

#### FIGURE 21-9: AUTO-WAKE-UP BIT (WUE) TIMINGS DURING SLEEP

#### 21.2.5 BREAK CHARACTER SEQUENCE

The EUSARTx module has the capability of sending the special Break character sequences that are required by the LIN/J2602 bus standard. The Break character transmit consists of a Start bit, followed by twelve '0' bits and a Stop bit. The Frame Break character is sent whenever the SENDB and TXEN bits (TXSTAx<3> and TXSTAx<5>, respectively) are set while the Transmit Shift Register is loaded with data. Note that the value of data written to TXREGx will be ignored and all '0's will be transmitted.

The SENDB bit is automatically reset by hardware after the corresponding Stop bit is sent. This allows the user to preload the transmit FIFO with the next transmit byte following the Break character (typically, the Sync character in the LIN/J2602 specification).

Note that the data value written to the TXREGx for the Break character is ignored. The write simply serves the purpose of initiating the proper sequence.

The TRMT bit indicates when the transmit operation is active or Idle, just as it does during normal transmission. See Figure 21-10 for the timing of the Break character sequence.

#### 21.2.5.1 Break and Sync Transmit Sequence

The following sequence will send a message frame header made up of a Break, followed by an Auto-Baud Sync byte. This sequence is typical of a LIN/J2602 bus master.

- 1. Configure the EUSARTx for the desired mode.
- 2. Set the TXEN and SENDB bits to set up the Break character.
- 3. Load the TXREGx with a dummy character to initiate transmission (the value is ignored).
- 4. Write '55h' to TXREGx to load the Sync character into the transmit FIFO buffer.
- 5. After the Break has been sent, the SENDB bit is reset by hardware. The Sync character now transmits in the preconfigured mode.

When the TXREGx becomes empty, as indicated by the TXxIF, the next data byte can be written to TXREGx.

#### 21.2.6 RECEIVING A BREAK CHARACTER

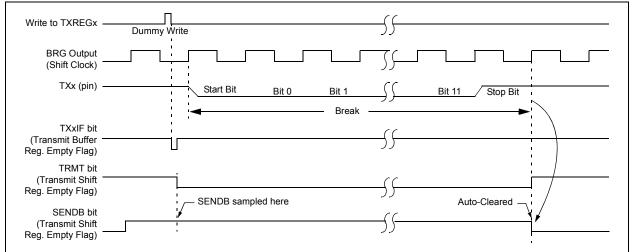

The Enhanced USART module can receive a Break character in two ways.

The first method forces configuration of the baud rate at a frequency of 9/13 the typical speed. This allows for the Stop bit transition to be at the correct sampling location (13 bits for Break versus Start bit and 8 data bits for typical data).

The second method uses the auto-wake-up feature described in Section 21.2.4 "Auto-Wake-up on Sync Break Character". By enabling this feature, the EUSARTx will sample the next two transitions on RXx/DTx, cause an RCxIF interrupt and receive the next data byte followed by another interrupt.

Note that following a Break character, the user will typically want to enable the Auto-Baud Rate Detect feature. For both methods, the user can set the ABDEN bit once the TXxIF interrupt is observed.

#### FIGURE 21-10: SEND BREAK CHARACTER SEQUENCE

#### 21.3 EUSARTx Synchronous Master Mode

The Synchronous Master mode is entered by setting the CSRC bit (TXSTAx<7>). In this mode, the data is transmitted in a half-duplex manner (i.e., transmission and reception do not occur at the same time). When transmitting data, the reception is inhibited and vice versa. Synchronous mode is entered by setting bit, SYNC (TXSTAx<4>). In addition, enable bit, SPEN (RCSTAx<7>), is set in order to configure the TXx and RXx pins to CKx (clock) and DTx (data) lines, respectively.

The Master mode indicates that the processor transmits the master clock on the CKx line. Clock polarity is selected with the TXCKP bit (BAUDCONx<4>). Setting TXCKP sets the Idle state on CKx as high, while clearing the bit sets the Idle state as low. This option is provided to support Microwire devices with this module.

#### 21.3.1 EUSARTx SYNCHRONOUS MASTER TRANSMISSION

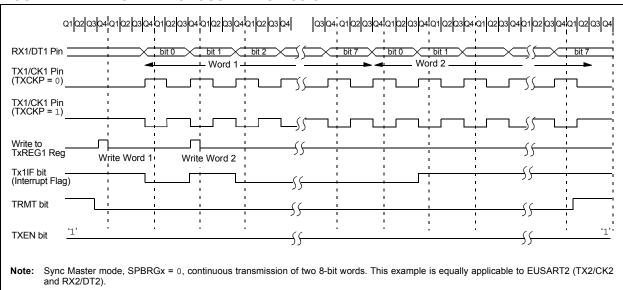

The EUSARTx transmitter block diagram is shown in Figure 21-3. The heart of the transmitter is the Transmit (Serial) Shift Register (TSR). The shift register obtains its data from the Read/Write Transmit Buffer register, TXREGx. The TXREGx register is loaded with data in software. The TSR register is not loaded until the last bit has been transmitted from the previous load. As soon as the last bit is transmitted, the TSR is loaded with new data from the TXREGx (if available).

Once the TXREGx register transfers the data to the TSR register (occurs in one TCY), the TXREGx is empty and the TXxIF flag bit is set. The interrupt can be enabled or disabled by setting or clearing the interrupt enable bit, TXxIE. TXxIF is set regardless of the state of enable bit, TXxIE; it cannot be cleared in software. It will reset only when new data is loaded into the TXREGx register.

While flag bit, TXxIF, indicates the status of the TXREGx register, another bit, TRMT (TXSTAx<1>), shows the status of the TSR register. TRMT is a read-only bit which is set when the TSR is empty. No interrupt logic is tied to this bit, so the user must poll this bit in order to determine if the TSR register is empty. The TSR is not mapped in data memory so it is not available to the user.

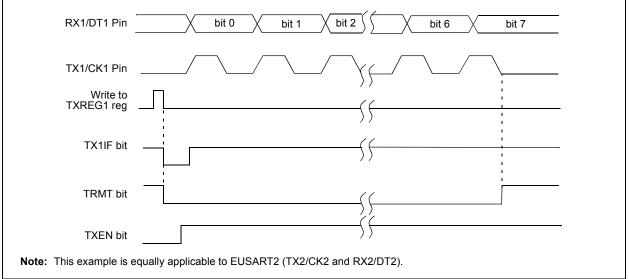

To set up a Synchronous Master Transmission:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRG16 bit, as required, to achieve the desired baud rate.
- 2. Enable the Master Synchronous Serial Port by setting bits, SYNC, SPEN and CSRC.
- 3. If interrupts are desired, set enable bit, TXxIE.
- 4. If 9-bit transmission is desired, set bit, TX9.
- 5. Enable the transmission by setting bit, TXEN.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit, TX9D.
- 7. Start transmission by loading data to the TXREGx register.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### FIGURE 21-11: SYNCHRONOUS TRANSMISSION

#### 21.3.2 EUSARTx SYNCHRONOUS MASTER RECEPTION

Once Synchronous mode is selected, reception is enabled by setting either the Single Receive Enable bit, SREN (RCSTAx<5>) or the Continuous Receive Enable bit, CREN (RCSTAx<4>). Data is sampled on the RXx pin on the falling edge of the clock.

If enable bit, SREN, is set, only a single word is received. If enable bit, CREN, is set, the reception is continuous until CREN is cleared. If both bits are set, then CREN takes precedence.

To set up a Synchronous Master Reception:

- 1. Initialize the SPBRGHx:SPBRGx registers for the appropriate baud rate. Set or clear the BRG16 bit, as required, to achieve the desired baud rate.
- 2. Enable the Master Synchronous Serial Port by setting bits, SYNC, SPEN and CSRC.

- 3. Ensure bits, CREN and SREN, are clear.
- 4. If interrupts are desired, set enable bit, RCxIE.
- 5. If 9-bit reception is desired, set bit, RX9.
- 6. If a single reception is required, set bit, SREN. For continuous reception, set bit, CREN.
- 7. Interrupt flag bit, RCxIF, will be set when reception is complete and an interrupt will be generated if the enable bit, RCxIE, was set.
- 8. Read the RCSTAx register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 9. Read the 8-bit received data by reading the RCREGx register.
- 10. If any error occurred, clear the error by clearing bit CREN.
- 11. If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### FIGURE 21-13: SYNCHRONOUS RECEPTION (MASTER MODE, SREN)

#### 21.4 EUSARTx Synchronous Slave Mode

Synchronous Slave mode is entered by clearing bit, CSRC (TXSTAx<7>). This mode differs from the Synchronous Master mode in that the shift clock is supplied externally at the CKx pin (instead of being supplied internally in Master mode). This allows the device to transfer or receive data while in any low-power mode.

#### 21.4.1 EUSARTx SYNCHRONOUS SLAVE TRANSMISSION

The operation of the Synchronous Master and Slave modes is identical, except in the case of Sleep mode.

If two words are written to the TXREGx and then the SLEEP instruction is executed, the following will occur:

- a) The first word will immediately transfer to the TSR register and transmit.
- b) The second word will remain in the TXREGx register.
- c) Flag bit, TXxIF, will not be set.
- d) When the first word has been shifted out of TSR, the TXREGx register will transfer the second word to the TSR and flag bit, TXxIF, will now be set.
- e) If enable bit, TXxIE, is set, the interrupt will wake the chip from Sleep. If the global interrupt is enabled, the program will branch to the interrupt vector.

To set up a Synchronous Slave Transmission:

- Enable the synchronous slave serial port by setting bits, SYNC and SPEN, and clearing bit, CSRC.
- 2. Clear bits, CREN and SREN.
- 3. If interrupts are desired, set enable bit, TXxIE.
- 4. If 9-bit transmission is desired, set bit, TX9.
- 5. Enable the transmission by setting enable bit, TXEN.
- 6. If 9-bit transmission is selected, the ninth bit should be loaded in bit, TX9D.
- 7. Start transmission by loading data to the TXREGx register.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### 21.4.2 EUSARTx SYNCHRONOUS SLAVE RECEPTION

The operation of the Synchronous Master and Slave modes is identical, except in the case of Sleep, or any Idle mode and bit, SREN, which is a "don't care" in Slave mode.

If receive is enabled by setting the CREN bit prior to entering Sleep or any Idle mode, then a word may be received while in this Low-Power mode. Once the word is received, the RSR register will transfer the data to the RCREGx register. If the RCxIE enable bit is set, the interrupt generated will wake the chip from the Low-Power mode. If the global interrupt is enabled, the program will branch to the interrupt vector.

To set up a Synchronous Slave Reception:

- Enable the Master Synchronous Serial Port by setting bits, SYNC and SPEN, and clearing bit, CSRC.
- 2. If interrupts are desired, set enable bit, RCxIE.
- 3. If 9-bit reception is desired, set bit, RX9.
- 4. To enable reception, set enable bit, CREN.
- Flag bit, RCxIF, will be set when reception is complete. An interrupt will be generated if enable bit, RCxIE, was set.
- Read the RCSTAx register to get the 9th bit (if enabled) and determine if any error occurred during reception.
- 7. Read the 8-bit received data by reading the RCREGx register.
- 8. If any error occurred, clear the error by clearing bit, CREN.
- If using interrupts, ensure that the GIE and PEIE bits in the INTCON register (INTCON<7:6>) are set.

#### 21.5 Infrared Support

This module provides support for two types of infrared USART port implementations:

- IrDA clock output to support an external IrDA encoder/decoder device
- Full implementation of the IrDa encoder and decoder as part of the USART logic

Since the 16x clock is required to perform the IrDA encoding, both by this module and the external transmitter, this feature only works in the 16x Baud Rate mode and is not available in the 4x mode.

#### 21.5.1 EXTERNAL IrDA SUPPORT – IRDA CLOCK OUTPUT

The 16x Baud Clock is provided on the BCLK (Baud Clock) pin if the EUSARTx is enabled (SPEN = 1); it is configured for Asynchronous mode (SYNC = 0) when Clock Source Select is active (CSRC = 1). Note that the BCLK can be active in regular or IrDA mode (IREN bit is ignored).

#### 21.5.1.1 BCLK Output

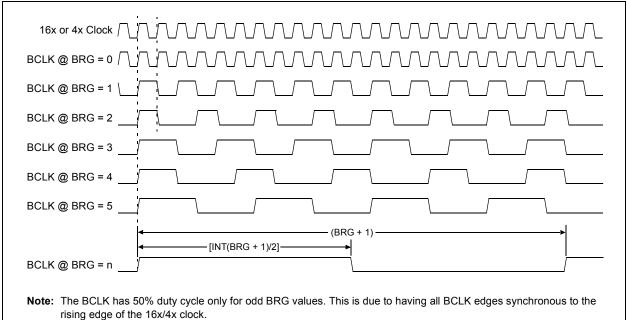

The timing of the Baud Clock (BCLK) output is independent of the 16x or 4x Baud Rate mode, resulting in the same output for a particular BRG value (since the 4x mode is four times faster, but has four times less pulses per period).

When the BCLK pin mode is active, the RXx Baud Rate Generator will be turned on, independent of a TXx or RXx operation. This will cause the RXx stream to synchronize to the already running RXx Baud Clock. This is acceptable only when BCLK is enabled for use.

The BCLK output goes inactive and stays low during Sleep mode.

The BCLK pin is taken over by the EUSARTx module and forced as an output, irrespective of port latch and TRIS latch bits. BCLK remains an output as long as USART is kept enabled in this mode.

#### FIGURE 21-14: BCLK OUTPUT vs. BRG PROGRAMMING

### 21.5.2 BUILT-IN IrDA ENCODER AND DECODER

The built-in IrDA encoder and decoder functionality is enabled using the IREN bit in the BAUDCONx register while the module is in Asynchronous mode (SYNC = 0). When enabled (IREN = 1), the Receive pin (RXx) acts as the input from the infrared receiver. The Transmit pin (TXx) acts as the output to the infrared transmitter. The 16x clock must be available for this feature to work properly.

The IrDA feature cannot be enabled for Synchronous modes (SYNC = 1).

#### 21.5.2.1 IrDA Encoder Function

The encoder works by taking the serial data from the USART and replacing it as follows:

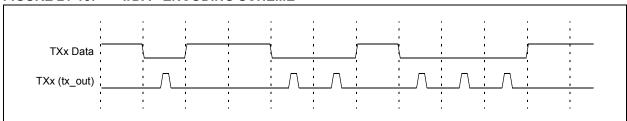

- Transmit bit data of '1' gets encoded as '0' for the entire 16 periods of the 16x Baud Clock
- Transmit bit data of '0' gets encoded as '0' for the first 7 periods of the 16x Baud Clock, then as '1' for the next 3 periods, and as '0' for the remaining 6 periods

See Figure 21-15 and Figure 21-17 for details.

#### 21.5.2.2 IrDA Transmit Polarity

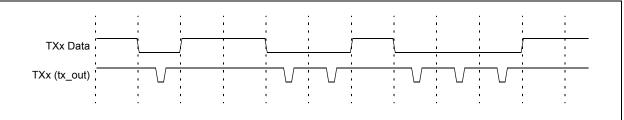

The IrDA transmit polarity is selected using the TXCKP bit. This bit only affects the transmit encoder and does not affect the receiver.

When TXCKP = 0, the Idle state of the TXx line is '0' (see Figure 21-15). When TXCKP = 1, the Idle state of the TXx line is '1' (see Figure 21-16).

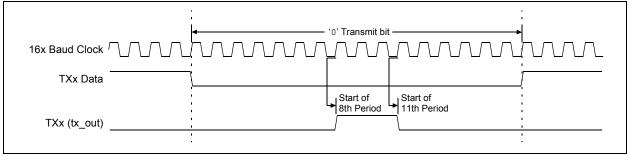

#### FIGURE 21-15: IrDA<sup>®</sup> ENCODING SCHEME

### FIGURE 21-16: INVERTED IrDA<sup>®</sup> ENCODING (TXCKP = 1)

### FIGURE 21-17: '0' BIT DATA IrDA<sup>®</sup> ENCODING SCHEME

#### 21.5.2.3 IrDA Decoder Function

The decoder works by taking the serial data from the RXx pin and replacing it with the decoded data stream. The stream is decoded based on falling edge detection of the RXx input.

Each falling edge of RXx causes the decoded data to be driven low for 16 periods of the 16x Baud Clock. If another falling edge has been detected by the time the 16 periods expire, the decoded data remains low for another 16 periods. If no falling edge was detected, the decoded data is driven high.

Note that the data stream into the device is shifted anywhere from 7 to 8 periods of the 16x Baud Clock from the actual message source. The one clock uncertainty is due to the clock edge resolution. See Figure 21-18 for details.

#### 21.5.2.4 IrDA Receive Polarity

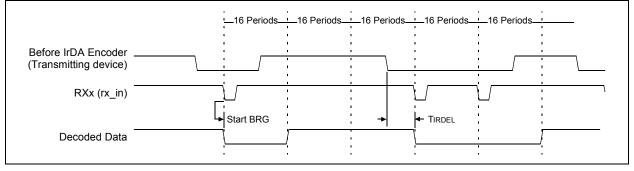

The IrDA receive polarity is selected using the RXDTP bit. This bit only affects the receive encoder and does not affect the transmitter.

When RXDTP = 0, the Idle state of the RXx line is '1' (see Figure 21-18). When RXDTP = 1, the Idle state of the RXx line is '0' (see Figure 21-19).

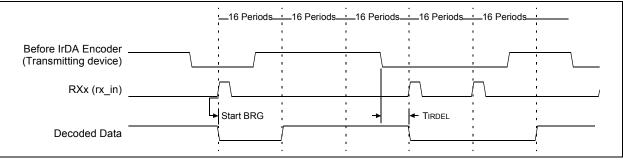

#### 21.5.2.5 Clock Jitter

Due to jitter or slight frequency differences between devices, it is possible for the next falling bit edge to be missed for one of the 16x periods. In that case, one clock-wide pulse appears on the decoded data stream. Since the EUSARTx performs a majority detect around the bit center, this does not cause erroneous data. See Figure 21-20 for details.

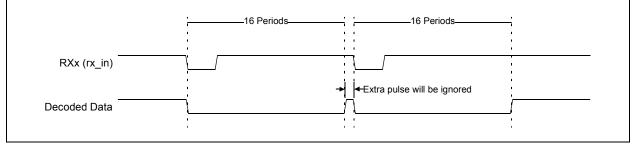

#### FIGURE 21-18: MACRO VIEW OF IrDA<sup>®</sup> DECODING SCHEME (RXDTP = 0)

#### FIGURE 21-19: INVERTED POLARITY DECODING RESULTS (RXDTP = 1)

#### FIGURE 21-20: CLOCK JITTER CAUSING A PULSE BETWEEN CONSECUTIVE ZEROS

#### 22.0 12-BIT A/D CONVERTER WITH THRESHOLD SCAN

The 12-bit A/D Converter has the following key features:

- Successive Approximation Register (SAR)
   Conversion
- Conversion Speeds of up to 200 ksps at 12 bits and 500 ksps at 10 bits
- Up to 32 Analog Input Channels (internal and external)
- · Selectable 10-Bit or 12-Bit (default) Conversion
- Resolution
- Multiple Internal Reference Input Channels
- External Voltage Reference Input Pins
- Unipolar Differential Sample-and-Hold (S/H) Amplifier
- Automated Threshold Scan and Compare Operation to Pre-Evaluate up to 26 Conversion Results
- Selectable Conversion Trigger Source
- Fixed Length (one word per channel), Configurable Conversion Result Buffer
- Four Options for Results Alignment
- Configurable Interrupt Generation
- · Operation During CPU Sleep and Idle modes

The 12-bit A/D Converter module is an enhanced version of the 10-bit module offered in some PIC18 devices. Both modules are Successive Approximation Register (SAR) Converters at their cores, surrounded by a range of hardware features for flexible configuration. This version of the module extends functionality by providing 12-bit resolution, a wider range of automatic sampling options, tighter integration with other analog modules, such as the CTMU, and a configurable results buffer. This module also includes a unique Threshold Detect feature that allows the module itself to make simple decisions based on the conversion results.

As before, an internal Sample-and-Hold (S/H) amplifier acquires a sample of an input signal, then holds that value constant during the conversion process. A combination of input multiplexers selects the signal to be converted from up to 32 analog inputs, both external (analog input pins) and internal (e.g., on-chip voltage references and other analog modules). The whole multiplexer path includes provisions for differential analog input, although, with a limited number of negative input pins. The sampled voltage is held and converted to a digital value, which strictly speaking, represents the ratio of that input voltage to a reference voltage. Configuration choices allow connection of an external reference or use of the device power and ground (AVDD and AVSS). Reference and input signal pins are assigned differently depending on the particular device.

An array of timing and control selections allow the user to create flexible scanning sequences. Conversions can be started individually by program control, continuously free-running or triggered by selected hardware events. A single channel may be repeatedly converted. Alternate conversions may be performed on two channels, or any or all of the channels may be sequentially scanned and converted according to a user-defined bit map. The resulting conversion output is a 12-bit digital number, which can be signed or unsigned, left or right justified. (In some devices, a user-selectable resolution of ten bits is available; in other devices, 10-bit resolution is the only option available.)

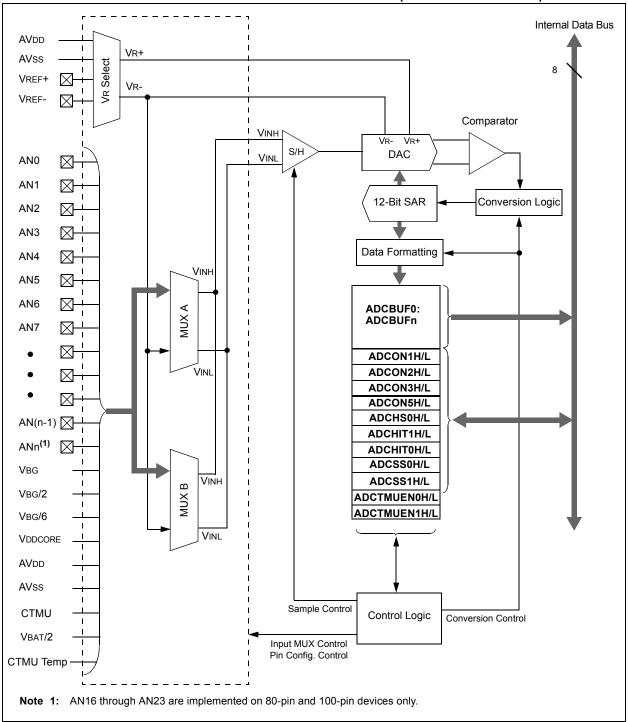

Conversions are automatically stored in a dedicated buffer, allowing for multiple successive readings to be taken before software service is needed. The buffer can be configured to function as a FIFO buffer or as a channel indexed buffer. In FIFO mode, the buffer can be split into two equal sections for simultaneous conversion and read operations. In Indexed mode, the buffer can use the Threshold Scan feature to determine if a conversion meets specific, user-defined criteria, storing or discarding the converted value as appropriate, and then set semaphore flags to indicate the event. This allows conversions to occur in low-power modes when the CPU is inactive, waking the device only when specific conditions have occurred.

The module sets its interrupt flag after a selectable number of conversions, when the buffer can be read, or after a successful Threshold Detect comparison. After the interrupt, the sequence restarts at the beginning of the buffer. When the interrupt flag is set, according to the earlier selection, scan selections and the Output Buffer Pointer return to their starting positions.

During Sleep or Idle mode, the A/D can wake-up at preconfigured intervals while the device maintains a Low-Power mode. If threshold conditions have not been met on any of the conversions, the module will return to a Low-Power mode.

The A/D module provides configuration to directly interact with the CTMU on specific input channels. This allows the CTMU to automatically turn on only when requested directly by the A/D, even though the rest of the device stays in Sleep mode.

A simplified block diagram for the module is shown in Figure 22-1.

#### 22.1 Registers

The 12-bit A/D converter module uses up to 75 registers for its operation. All registers are mapped in the data memory space.

#### 22.1.1 CONTROL REGISTERS

Depending on the specific device, the module has up to twelve control and STATUS registers:

- ADCON1H/L: A/D Control Registers
- ADCON2H/L: A/D Control Registers
- ADCON3H/L: A/D Control Registers
- ADCON5H/L: A/D Control Registers
- ADCHS0H/L: A/D Input Channel Select Registers
- ADCHITH1H/L and ADCHITH0H/L: A/D Scan Compare Hit Registers
- ADCSS1H/L and ADCSS0H/L: A/D Input Scan Select Registers
- ADCTMUEN1H/L and ADCTMUEN0H/L: CTMU Enable Register

The ADCON1H/L, ADCON2H/L and ADCON3H/L registers control the overall operation of the A/D module. This includes enabling the module, configuring the conversion clock and voltage reference sources, selecting the sampling and conversion triggers, and manually controlling the sample/convert sequences. The ADCON5H/L registers specifically controls features of Threshold Detect operation, including its functioning in power-saving modes.

The ADCHS0H/L registers selects the input channels to be connected to the S/H amplifier. It also allows the choice of input multiplexers and the selection of a reference source for differential sampling.

The ADCHITH1H/L and ADCHITH0H/L registers are semaphore registers used with Threshold Detect operations. The status of individual bits, or bit pairs in some cases, indicate if a match condition has occurred. Their use is described in more detail in Section 22.7 "Threshold Detect Operation". ADCHITH0H/L is always implemented, whereas ADCHITH1H/L may not be implemented in devices with 16 channels or less. The ADCSS0H/L/L registers select the channels to be included for sequential scanning. The ADCTMUEN1H/ L/L registers select the channel(s) to be used by the CTMU during conversions. Selecting a particular channel allows the A/D Converter to control the CTMU (particularly, its current source) and read its data through that channel. ADCTMUEN0H/L is always implemented, whereas ADCTMUEN1H/L may not be implemented in devices with 16 channels or less.

#### 22.1.2 A/D RESULT BUFFERS

The module incorporates a multi-word, dual port RAM, called ADCBUF. The buffer is composed of at least the same number of word locations as there are external analog channels for a particular device, with a maximum number of 26. The number of buffer addresses is always even. Each of the locations is mapped into the data memory space and is separately addressable. The buffer locations are referred to as ADCBUF0H/L through ADCBUFnH/L (up to 26).

The A/D result buffers are both readable and writable. When the module is active (ADCON1H<7> = 1), the buffers are read-only, and store the results of A/D conversions. When the module is inactive (ADCON1H<7> = 0), the buffers are both readable and writable. In this state, writing to a buffer location programs a conversion threshold for Threshold Detect operations, as described in Section 22.7.2, Setting Comparison Thresholds.

- Note 1: These input channels do not have corresponding memory mapped result buffers.
  - 2: These channels are implemented in 80-pin and 100-pin devices only.
  - **3:** For accurately sampling the band gap set SMPI bits in ADCON2L register to 0, so that the ADC samples the band gap only once on every trigger. When the band gap is sampled multiple times, a large capacitive load is connected to the output of the band gap multiple times, which could cause the output to become unstable for a while and an overshoot or undershoot could be sampled.

# 22.2 A/D Terminology and Conversion Sequence

Sample time is the time that the A/D module's S/H amplifier is connected to the analog input pin. The sample time may be started and ended automatically by the A/D Converter's hardware or under direct program control. There is a minimum sample time to ensure that the S/H amplifier will give sufficient accuracy for the A/D conversion.

The conversion trigger ends the sampling time and begins an A/D conversion or a repeating sequence. The conversion trigger sources can be taken from a variety of hardware sources or can be controlled directly in software. One of the conversion trigger options is an auto-conversion, which uses a counter and the A/D clock to set the time between auto-conversions. The Auto-Sample mode and auto-conversion trigger can be used together to provide continuous, automatic conversions without software intervention. When automatic sampling is used, an extended sampling interval is extended between the time the sampling ends and the conversion starts.

Conversion time is the time required for the A/D Converter to convert the voltage held by the S/H amplifier. An A/D conversion requires one A/D clock cycle (TAD) to convert each bit of the result, plus two additional clock cycles, or a total of 14 TAD cycles for a 12bit conversion. When the conversion is complete, the result is loaded into one of the A/D result buffers. The S/H can be reconnected to the input pin and a CPU interrupt may be generated. The sum of the sample time(s) and the A/D conversion time provides the total A/D sequence time. Figure 22-2 shows the basic conversion sequence and the relationship between intervals.

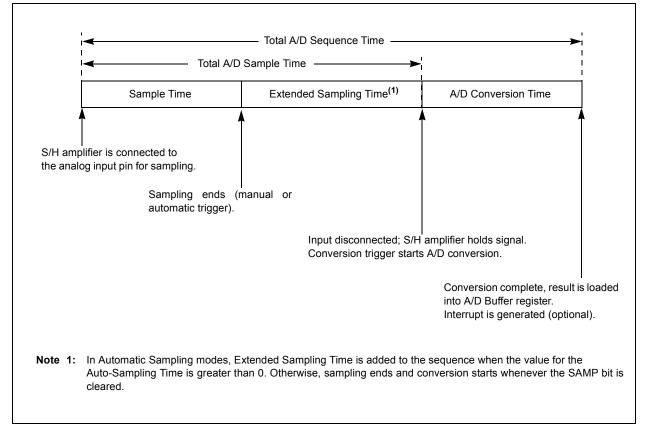

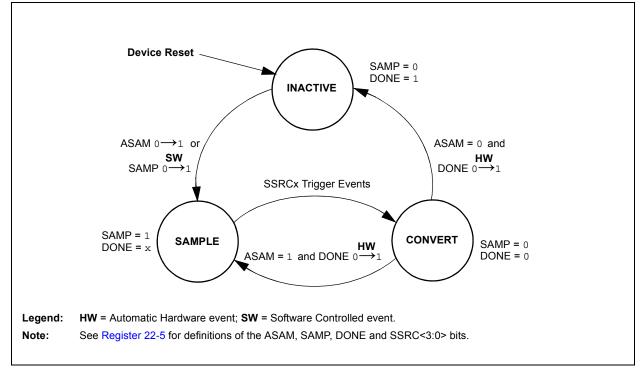

FIGURE 22-2: A/D SAMPLE/CONVERT SEQUENCE

### 22.2.1 OPERATION AS A STATE MACHINE

The A/D conversion process can be thought of in terms of a finite state machine (Figure 22-3). The sample state represents the time that the input channel is connected to the S/H amplifier and the signal is passed to the converter input. The convert state is transitory. The module enters this state as soon as it exits the sample state and transitions to a different state when that is done. The inactive state is the default state prior to module initialization and following a software-controlled conversion; it can be avoided in operation by using Auto-Sample mode. Machine states are identified by the state of several control and Status bits in ADCON1H/L. If the module is configured for Auto-Sample mode, the operation "ping-pongs" continuously between the sample and convert states. The module automatically selects the input channels to be sampled (if channel scanning is enabled), while the selected conversion trigger source paces the entire operation. Any time that Auto-Sample mode is not used for conversion, it is available for the sample state. The user needs to make certain that acquisition time is sufficient, in addition to accounting for the normal concerns about system throughput.

Whenever the issue of sampling time is important, the significant event is the transition from sample to convert state. This is the point where the Sample-and-Hold aperture closes, and it is essentially the signal value at this instant, which is applied to the A/D for conversion to digital.

### FIGURE 22-3: A/D MODULE STATE MACHINE MODEL

# 22.3 A/D Module Configuration

All of the registers described in the previous section must be configured for module operation to be fully defined. An effective approach is first, to describe the signals and sequences for the particular application. Typically, it is an iterative process to assign signals to port pins, to establish timing methods and to organize a scanning scheme, as well as to integrate the whole process with the software design.

The various configuration and control functions of the module are distributed throughout the module's six control registers. Control functions can be broadly sorted into four groups: input, timing, conversion and output. Table 22-1 shows the register location of control or Status bits by register.

A/D Function	Register(s)	Specific Bits
Input	ADCON2H/L	PVCFG<1:0>, NVCFG, OFFCAL, CSCNA, ALTS
	ADCHS0H/L	CH0NB<2:0>, CH0SB<4:0>, CH0NA<2:0>, CH0SA<4:0>
	ADCSS0H/L	CSS<15:0>
	ADCSS1H/L	CSS<30:16>
	ADCTMEN0H/L	CTMEN<15:0>
	ADCTMEN1H/L	CTMEN<31:16>
Conversion	ADCON1H/L	ADON, SSRC<3:0>, ASAM, SAMP, DONE, MODE12
	ADCON2H/L	SMPI<4:0>
	ADCON3H/L	EXTSAM
	ADCON5H/L	ASEN, LPENA, ASINTMD<1:0>
Timing	ADCON3H/L	ADRC, SAMC<4:0>, ADCS<7:0>
Output	ADCON1H/L	FORM<1:0>
	ADCON2H/L	BUFS, BUFM, BUFREGEN
	ADCON5H/L	WM<1:0>, CM<1:0>

Note:	Do not write to the SSRCx, BUFS, SMPIx,
	BUFM and ALTS bits, or the ADCON3H/L,
	and ADCSS0H/L registers, while
	ADON = 1; otherwise, indeterminate con-
	version data may result.

The following steps should be followed for performing an A/D conversion:

- 1. Configure the A/D module:
  - Select the output resolution (if configurable)
  - Select the voltage reference source to match the expected range on analog inputs
  - Select the analog conversion clock to match the desired data rate with a processor clock
  - Determine how sampling will occur
  - Set the multiplexer input assignments
  - Select the desired sample/conversion sequence
  - Select the output data format
  - Select the output value destination
  - Select the number of readings per interrupt

- 2. Configure the A/D interrupt (if required):
  - Clear the ADIF bit
  - Select the A/D interrupt priority
- 3. Turn on the A/D module.

The options for each configuration step are described in the subsequent sections.

# 22.3.1 SELECTING THE RESOLUTION

The MODE12 bit (ADCON1H<3>) controls output resolution. Setting this bit selects 12-bit resolution.

### 22.3.2 SELECTING THE VOLTAGE REFERENCE SOURCE

The voltage references for A/D conversions are selected using the PVCFG<1:0> and NVCFG0 control bits (ADCON2H<7:5>). The upper voltage reference (VR+) may be AVDD, the external VREF+ or an internal band gap reference voltage. The lower voltage reference (VR-) may be AVSS or the VREF- input pin. The available options vary between device families.

The external voltage reference pins may be shared with the AN2 and AN3 inputs on low pin count devices. The A/D Converter can still perform conversions on these pins when they are shared with the VREF+ and VREF- input pins.

The voltages applied to the external reference pins must meet certain specifications. Refer to the device data sheet for further details.

### 22.3.3 SELECTING THE A/D CONVERSION CLOCK

The A/D Converter has a maximum rate at which conversions may be completed. An analog module clock, TAD, controls the conversion timing. The A/D conversion requires 14 clock periods (14 TAD) for a 12-bit conversion and 12 clock periods (12 TAD) for a 10-bit conversion. The A/D clock is derived from the device instruction clock.

The period of the A/D conversion clock is software selected using a 6-bit counter. There are 64 possible options for TAD, specified by the ADCSX bits in the ADCON3L register. Equation 22-1 gives the TAD value as a function of the ADCSx control bits and the device instruction cycle clock period, TCY. For correct A/D conversions, the A/D conversion clock (TAD) must be selected to ensure a minimum TAD time, as specified by the device family data sheet.

# EQUATION 22-1: A/D CONVERSION CLOCK PERIOD

TAD = 2/Fosc (ADCS + 1) $ADCS = \frac{TAD}{2/Fosc} - 1$ 

```
Note: PLL is disabled.
```

The A/D Converter also has its own dedicated RC clock source that can be used to perform conversions. The A/D RC clock source should be used when conversions are performed while the device is in Sleep mode. The RC oscillator is selected by setting the ADRC bit (ADCON3H<7>). When the ADRC bit is set, the ADCSx bits have no effect on A/D operation.

### 22.3.4 CONFIGURING ANALOG PORT PINS

The A/D module does not have an internal provision to configure port pins for analog operation. Instead, input pins are configured as analog inputs through the Analog Select registers (ANSn, where 'n' is the port name). A pin is configured as an analog input when the corresponding ANSn bit is set. By default, pins with multiplexed analog and digital functions are configured as analog pins on device Reset.

For external analog inputs, both the ANSn register and the corresponding TRIS register bits control the operation of the A/D port pins. The port pins that will function as analog inputs must also have their corresponding TRIS bits set, specifying the pins as inputs. After a device Reset, all TRIS bits are set. If the I/O pin associated with an A/D channel is configured as a digital output (TRIS bit is cleared), while the pin is configured for Analog mode, the port digital output level (VOH or VOL) will be converted.

- **Note 1:** When reading a PORT register, any pin configured as an analog input reads as '0'.
  - 2: Analog levels on any pin that is defined as a digital input may cause the input buffer to consume current that is out of the device's specification.

# 22.3.5 INPUT CHANNEL SELECTION

The A/D Converter incorporates two independent sets of input multiplexers (MUX A and MUX B) that allow users to choose which analog channels are to be sampled. The inputs specified by the CH0SAx and CH0NAx bits are collectively called the MUX A inputs. The inputs specified by the CH0SBx and CH0NBx bits are collectively called the MUX B inputs.

Functionally, MUX A and MUX B are very similar to each other. Both multiplexers allow any of the analog input channels to be selected for individual sampling and allow selection of a negative reference source for differential signals. In addition, MUX A can be configured for sequential analog channel scanning. This is discussed in more detail in Section 22.3.5.1 "Configuring MUX A And MUX B Inputs" and Section 22.3.5.3 "Scanning Through Several Inputs".

```
Note: Different PIC18F devices will have different numbers of analog inputs. Verify the analog input availability against the particular device's data sheet.
```

### 22.3.5.1 Configuring MUX A And MUX B Inputs

The user may select any one of up to 32 inputs available to the A/D Converter as the positive input of the S/ H amplifier. For MUX A, the CH0SA<4:0> bits (ADCHS0L<4:0>) normally select the analog channel for the positive input. For MUX B, the positive channel is selected by the CH0SB<4:0> bits (ADCHS0H<4:0>).

All of the external analog channels are available as positive inputs. In addition to the external inputs, these may also include device supply voltage (AVDD), the logic core supply voltage (VDDCORE), the internal band gap voltage (VBG) and/or multiples or fractions of VBG. One or more additional input channels are used for the CTMU. These selections leave the A/D disconnected from all other inputs. The options vary by device family; refer to the specific device data sheet for details. The CTMU input is selected by the ADCTMUEN1H/L, ADCTMUEN0H/L registers. Setting a particular bit in one of these registers effectively assigns the analog output from the CTMU to the corresponding A/D input channel, automatically enabling the CTMU. Many devices will already have a CH0SAx bit combination designated for use of the CTMU. This setting disconnects the converter from any other load. This channel should be the one selected by the appropriate ADCTMUEN bit. If another channel is selected, verify that any other analog sources are disconnected from that channel; otherwise, erroneous readings may result.

For the negative (inverting) input of the amplifier, the user has up to eight options, selected by the CH0NA<2:0> and CH0NB<2:0> bits (ADCHS0L<7:5> and ADCHS0H<7:5>, respectively). Options typically include the device ground (AVSS), the current VR-source designated by the NVCFG0 bit (ADCON2H<5>), and one or more of the external analog input channels. As with the non-inverting inputs, the options vary by device family.

# 22.3.5.2 Alternating MUX A And MUX B Input Selections

By default, the A/D Converter only samples and converts the inputs selected by MUX A. The ALTS bit (ADCON2L<0>) enables the module to alternate between two sets of inputs selected by MUX A and MUX B during successive samples.

If the ALTS bit is '0', only the inputs specified by the CH0SAx and CH0NAx bits are selected for sampling. When the ALTS bit is '1', the module will alternate between the MUX A inputs on one sample and the MUX B inputs on the subsequent sample.

If the ALTS bit is '1' on the first sample/convert sequence, the inputs specified by the CH0SAx and CH0NAx bits are selected for sampling. On the next sample/convert sequence, the inputs specified by the CH0SBx and CH0NBx bits are selected for sampling. This pattern repeats for subsequent sample conversion sequences.

# 22.3.5.3 Scanning Through Several Inputs

When using MUX A to select analog inputs, the A/D module has the ability to scan multiple analog channels. When the CSCNA bit (ADCON2H<>) is set, the CH0SA bits are ignored and the channels specified by the ADCSS1H/L, ADCSS0H/L registers are sequentially sampled.

Each bit in the ADCSS1H/L registers and ADCSS0H/L registers (when implemented) corresponds to one of the analog channels. If a bit in the ADCSS0H/L or ADCSS1H/L registers is set, the corresponding analog channel is included in the scan sequence. Inputs are

always scanned from lower to higher numbered inputs, starting at the first selected channel after each interrupt occurs.

Note 1: If the number of scanned inputs selected is greater than the number of samples taken per interrupt, the higher numbered inputs will not be sampled.

2: If the CTMU channel is to be included in a scan operation, verify that the proper analog input channel is selected and that the AD1CTMEN register(s) are correctly configured. For more information, see Section 22.3.5.1 "Configuring MUX A And MUX B Inputs".

The ADCSS1H/L, ADCSS0H/L registers' bits specify the positive input of the channel. The CH0NAx bits still select the negative input of the channel during scanning.

Scanning is only available on the MUX A input selection. The MUX B input selection, as specified by the CH0SBx bits, will still select the alternating input. When alternated sampling between MUX A and MUX B is selected (ALTS = 1), the input will alternate between a set of scanning inputs specified by the ADCSS1H/L, ADCSS0H/L registers, and a fixed input specified by the CH0SBx bits.

Automatic scanning can be used in conjunction with the Threshold Detect feature to determine if one or more analog channels meet a predetermined set of conditions while the CPU is inactive. This is described in detail in Section 22.7 "Threshold Detect Operation".

### 22.3.5.4 Internal Channels In Low-power Modes

While the A/D module can scan and convert analog inputs in low-power modes, some internal analog inputs may be unavailable in Sleep mode. The main examples are the CTMU module, the internal band gap voltage source and the on-chip voltage regulator (for those devices that include one). The A/D module provides a method to make these resources available automatically through the CTMUREQ bit (ADCON5H<5>). Setting one or more of these bits causes the corresponding internal analog source(s) to become active during a channel scan.

# 22.3.6 ENABLING THE MODULE

When the ADON bit (ADCON1H<7>) is set, the module is fully powered and functional. When ADON is '0', the module is disabled. Although the digital and analog portions of the circuit are turned off for maximum current savings, the contents of all registers are maintained.

Conversion data stored in the ADCBUF registers will also be maintained, including any threshold values stored by the user. It may be necessary to re-initialize these registers to their proper values before reenabling the module.

When enabling the module by setting the ADON bit, the user must wait for the analog stages to stabilize. For the stabilization time, refer to **Section 30.0 "Electrical Specifications"**.

# 22.4 Controlling the Sampling Process

# 22.4.1 MANUAL SAMPLING

Setting the SAMP bit (ADCON1L<1>) while the ASAM bit (ADCON1L<2>) is clear causes the A/D to begin sampling. Clearing the SAMP bit ends sampling and automatically begins the conversion; however, there must be a sufficient delay between setting and clearing SAMP for the sampling process to start. Sampling will not resume until the SAMP bit is once again set. For an example, see Figure 22-4.

# 22.4.2 AUTOMATIC SAMPLING

Setting the ASAM bit causes the A/D to automatically begin sampling after a conversion has been completed. One of several options can be used as an event to end sampling and complete the conversions. Sampling will continue on the next selected channel after the conversion in progress has completed. For an example, see Figure 22-5.

# 22.4.3 MONITORING SAMPLE STATUS

The SAMP bit indicates the sampling state of the A/D. Generally, when the SAMP bit clears, indicating the end of sampling, the DONE bit is automatically cleared to indicate the start of conversion. If SAMP is '0' while DONE is '1', the A/D is in an inactive state.

# 22.4.4 ABORTING A SAMPLE

While in Manual Sampling mode, clearing the SAMP bit will terminate sampling. If SSRC<3:0> = 0000, it may also start a conversion automatically.

Clearing the ASAM bit while in Automatic Sampling mode will not terminate an ongoing sample/convert sequence; however, sampling will not automatically resume after a subsequent conversion.

### 22.5 Controlling the Conversion Process

The conversion trigger source will terminate sampling and start a selected sequence of conversions. The SSRC<3:0> bits (ADCON1L<7:4>) select the source of the conversion trigger.

- Note 1: The available conversion trigger sources may vary depending on the PIC18F device variant. Refer to the specific device data sheet for the available conversion trigger sources.
  - 2: The SSRCx selection bits should not be changed when the A/D module is enabled. If the user wishes to change the conversion trigger source, disable the A/D module first by clearing the ADON bit (AD1CON1<15>).

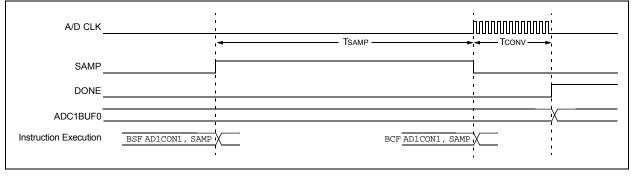

# 22.5.1 MANUAL CONTROL

When SSRC<3:0> = 0000, the conversion trigger is under software control. Clearing the SAMP bit (ADCON1L<1>) starts the conversion sequence.

Figure 22-4 is an example where setting the SAMP bit initiates sampling, and clearing the SAMP bit terminates sampling and starts conversion. The user software must time the setting and clearing of the SAMP bit to ensure adequate sampling time of the input signal.

Figure 22-5 is an example where setting the ASAM bit initiates automatic sampling, and clearing the SAMP bit terminates sampling and starts conversion. After the conversion completes, the module sets the SAMP bit and returns to the sample state. The user software must time the clearing of the SAMP bit to ensure

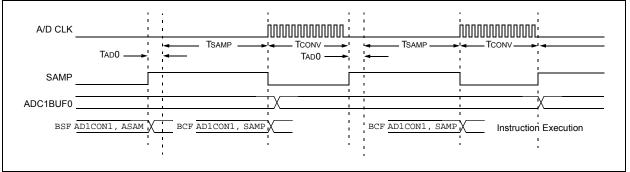

# FIGURE 22-4: CONVERTING ONE CHANNEL, MANUAL SAMPLE START, MANUAL CONVERSION START

# EXAMPLE 22-1: CONVERTING ONE CHANNEL, MANUAL SAMPLE START, MANUAL CONVERSION START CODE

```
int ADCValue;
ANCON1 = 0 \times 02;
                                   // AN2 as analog, all other pins are digital
ADCON1L = 0 \times 00;
                                   // SAMP bit = 0 ends sampling and starts converting
ADCHSOL = 0x02;
                                   // Connect AN2 as S/H+ input
                                   // in this example AN2 is the input
ADCSSOL = 0;
ADCON3L = 0 \times 02;
                                   // Manual Sample, Tad = 3Tcy
ADCON2L = 0;
ADCON1Hbits.ADON = 1;
                                   // turn ADC ON
while (1)
                                   // repeat continuously
{
   ADCON1Hbits.SAMP = 1;
                                   // start sampling...
   Delay();
                                   // Ensure the correct sampling time has elapsed
                                   // before starting conversion.
   ADCON1Hbits.SAMP = 0;
                                   // start converting
   while (!ADCON1Lbits.DONE){}; // conversion done?
   ADCValue = ADCBUF0;
                                   // yes then get ADC value
```

# FIGURE 22-5: CONVERTING ONE CHANNEL, AUTOMATIC SAMPLE START, MANUAL CONVERSION START

### 22.5.2 CLOCKED CONVERSION TRIGGER

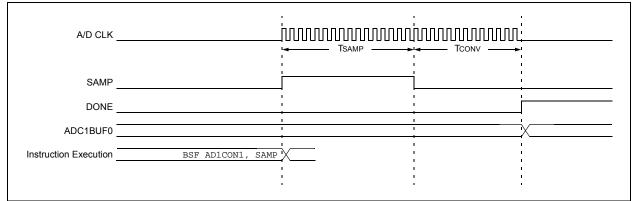

When ADRC = 1, the conversion trigger is under A/D clock control. The SAMCx bits (ADCON3H<4:0>) select the number of TAD clock cycles between the start of sampling and the start of conversion. After the start of sampling, the module will count a number of TAD clocks specified by the SAMCx bits. The SAMCx bits must always be programmed for at least one clock cycle to ensure sampling requirements are met.

### EQUATION 22-2: CLOCKED CONVERSION TRIGGER TIME

TSMP = SAMC<4:0> \* TAD

Figure 22-6 shows how to use the clocked conversion trigger with the sampling started by the user software.

# FIGURE 22-6: CONVERTING ONE CHANNEL, MANUAL SAMPLE START, TAD-BASED CONVERSION START

# EXAMPLE 22-2: CONVERTING ONE CHANNEL, MANUAL SAMPLE START, TAD-BASED CONVERSION START CODE

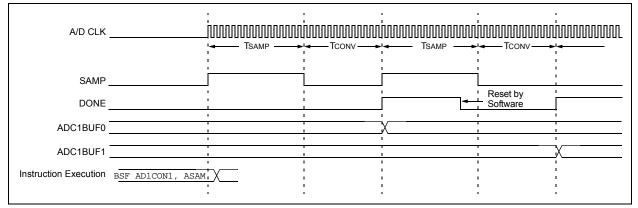

```
int ADCValue;
ANCON2 = 0 \times 10;
                                        // all PORTB = Digital; RB12 = analog
                                        // SSRC<2:0> = 111 implies internal counter ends sampling
ADCON1L = 0 \times 70;
                                        // and starts converting.
ADCHSOL = 0 \times 0C;
                                        // Connect AN12 as S/H input.
                                        // in this example AN12 is the input
ADCSSOH = 0;
                                        // Sample time = 31Tad, Tad = 3Tcy
ADCON3H = 1F;
ADCON3L=02;
ADCON2L = 0;
                                        // turn ADC ON
ADCON1Hbits.ADON = 1;
while (1)
                                        // repeat continuously
{
   ADCON1Lbits.SAMP = 1;
                                       // start sampling, then after 31Tad go to conversion
   ADCONILbits.SAMP = 1; // start sampling, t
while (!ADCONILbits.DONE){}; // conversion done?
   ADCValue = ADCBUF0;
                                        // yes then get ADC value
}
                                        // repeat
```

# 22.5.2.1 Free-running Sample Conversion Sequence

Using the Auto-Convert Conversion Trigger mode (SSRC<3:0> = 0111), in combination with the Auto-Sample Start mode (ASAM = 1), allows the A/D module to schedule sample/conversion sequences with no intervention by the user or other device resources. This "Clocked" mode, shown in Figure 22-7, allows continuous data collection after module initialization.

Note that all timing in this mode scales with TAD, either from the A/D internal RC clock or from TCY (as prescaled by the ADCS<7:0> bits). In both cases, the SAMC<4:0> bits set the number of TAD clocks in TSAMP. TCONV is fixed at 12 TAD.

### FIGURE 22-7: CONVERTING ONE CHANNEL, AUTO-SAMPLE START, TAD-BASED CONVERSION START

### 22.5.2.2 Sample Time Considerations Using Clocked Conversion Trigger And Automatic Sampling

The user must ensure the sampling time satisfies the sampling requirements, as outlined in Section 22.9 "A/ D Sampling Requirements". Assuming that the module is set for automatic sampling and using a clocked conversion trigger, the sampling interval is specified by the SAMCx bits.

### 22.5.3 EVENT TRIGGER CONVERSION START

It is often desirable to synchronize the end of sampling and the start of conversion with some other time event. Depending on the device family, the A/D module has up to 16 sources available to use as a conversion trigger event. The event trigger is selected by the SSRC<3:0> bits (ADCON1L<7:4>).

As noted, the available event triggers vary between device families. Refer to the specific device data sheet for specific information. The examples that follow represent trigger sources that are implemented in most devices. Note that the SSRCx bit assignments may vary in some devices.

# 22.5.3.1 External Int0 Pin Trigger

When SSRC<3:0> = 0001, the A/D conversion is triggered by an active transition on the INTO pin. The pin may be programmed for either a rising edge input or a falling edge input.

# 22.5.3.2 Special Event Trigger

When SSRC<3:0> = 0010, the A/D is triggered by a Special Event Trigger. Refer to CCP and ECCP section for more information about Special Event Triggers.

### 22.5.3.3 Synchronizing A/D Operations To Internal Or External Events

The modes where an external event trigger pulse ends sampling and starts conversion may be used in combination with auto-sampling (ASAM = 1) to cause the A/ D to synchronize the sample conversion events to the trigger pulse source. For example, in Figure 22-9, where SSRC<3:0> = 0010 and ASAM = 1, the A/D will always end sampling and start conversions synchronously with the timer compare trigger event. The A/D will have a sample conversion rate that corresponds to the timer comparison event rate.

### 22.5.3.4 Sample Time Considerations For Automatic Sampling/conversion Sequences

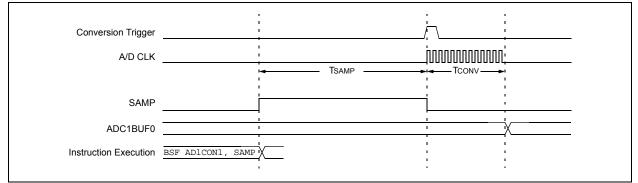

Different sample/conversion sequences provide different available sampling times for the S/H channel to acquire the analog signal. The user must ensure the sampling time satisfies the sampling requirements, as outlined in Section 22.9 "A/D Sampling Requirements".

Assuming that the module is set for automatic sampling, and an external trigger pulse is used as the conversion trigger, the sampling interval is a portion of the trigger pulse interval. The sampling time is the trigger pulse period, less the time required to complete the conversion.

### EQUATION 22-3: CALCULATING AVAILABLE SAMPLING TIME FOR SEQUENTIAL SAMPLING

TSMP = Trigger Pulse Interval (TSEQ) – Conversion Time (TCONV) = TSEQ – TCONV

### FIGURE 22-8: MANUAL SAMPLE START, CONVERSION TRIGGER-BASED CONVERSION START

### FIGURE 22-9: AUTO-SAMPLE START, CONVERSION TRIGGER-BASED CONVERSION START

Conversion Trigger A/D CLK		
SAMP	P Reset by	
DONE	Software	
ADC1BUF0		
ADC1BUF1		
BSF A		

### 22.5.4 MONITORING SAMPLE/ CONVERSION STATUS

The DONE bit (ADCON1L<0>) indicates the conversion state of the A/D. Generally, when the SAMP bit clears, indicating the end of sampling, the DONE bit is automatically cleared to indicate the start of conversion. If SAMP is '0' while DONE is '1', the A/D is in an inactive state.

In some operational modes, the SAMP bit may also invoke and terminate sampling. In these modes, the DONE bit cannot be used to terminate conversions in progress.

### 22.5.5 GENERATING A/D INTERRUPTS

The SMPI<4:0> bits (ADCON2L<6:2>) control the generation of the A/D Interrupt Flag, ADIF. The A/D Interrupt Flag is set after the number of sample/conversion sequences is specified by the SMPIx bits, after the start of sampling, and continues to recur after that number of samples. The value specified by the SMPIx bits also corresponds to the number of data samples in the buffer, up to the maximum of 16. To enable the interrupt, it is necessary to set the A/D Interrupt Enable bit, ADIE.

If auto-scan is enabled (ADCON5<7> = 1), interrupt generation is controlled by the ASINTMDx bits (ADCON5H<1:0>). For more information, refer to Section 22.7.4 "Threshold Detect Interrupts".

# 22.5.6 ABORTING A CONVERSION

Clearing the ADON bit during a conversion will abort the current conversion. The A/D results buffer will not be updated with the partially completed A/D conversion sample; that is, the corresponding ADCBUF buffer location will continue to contain the value of the last completed conversion (or the last value written to the buffer).

# 22.5.7 OFFSET CALIBRATION

The module provides a simple calibration method to offset the effects of internal device noise. While not always necessary, this may be helpful in situations where weak analog signals are being converted. Calibration is performed by using the OFFCAL bit (ADCON2H<4>). This disconnects the S/H amplifier entirely from any inputs. With the OFFCAL bit set, a single reference conversion is performed. The results of this conversion are value added by internal device noise. This result can be stored by the application, then used as an offset value for future conversions.

# 22.6 A/D Results Buffer

As conversions are completed, the module writes the results of the conversions into the A/D result buffer. This buffer is a RAM array of fixed word size, accessed through the SFR space. The size of the buffer is determined by the number of external analog input channels on the device, allowing one word for each channel. Depending on the device, additional buffer space may be provided for one or more internal analog channels (e.g., band gap sources). The number of buffer addresses is always even and always at least equal to the number of external channels.

User software may attempt to read each A/D conversion result as it is generated; however, this might consume too much CPU time. Generally, to minimize software overhead, the module will fill the buffer with results and then generate an interrupt when the buffer is filled.

Note:	This section describes buffer operation in
	Legacy mode (ADCON5L<3:2> = $00$ ).
	Buffer operation is different when the
	Compare Only or Compare and Save
	modes are used with the Threshold Detect
	feature. For more information, see Section
	22.7 "Threshold Detect Operation".

### 22.6.1 NUMBER OF CONVERSIONS PER INTERRUPT

The SMPI<4:0> bits select how many A/D conversions will take place before the CPU is interrupted. This can vary from 1 to 16 samples per interrupt. The A/D Converter module always starts writing its conversion results at the beginning of the buffer, after each interrupt. For example, if SMPI<4:0> = 00000, the conversion results will always be written to the ADC-BUF0. In this example, no other buffer locations would be used, since only one sequence per interrupt is specified.

# 22.6.2 BUFFER FILL MODES

The results buffer can be configured to operate in either of two modes: a standard FIFO mode, compatible with the earlier 10-bit A/D module (default), or a Channel Indexed mode. The Fill mode is selected by the BUFREGEN bit (ADCON2H<3>).

### 22.6.2.1 FIFO Modes

When BUFREGEN = 0, the results buffer operates in FIFO mode. The first conversion results, after initiating conversions, is written to the first available buffer address. Subsequent conversions are written to the next sequential buffer location, continuing until the process is interrupted. If allowed to continue without interrupts, the module would fill each location and then wrap around to the first address, continuing the process.

The BUFM bit (ADCON2L<1>) controls how the buffer is filled. When BUFM is '1', the buffer is split into two equal halves: a lower half (ADCBUF0 through ADC-BUF[(n/2) - 1]) and an upper half (ADCBUF[n/2] through ADCBUFn), where n is the number of available analog channels (both internal and external). The buffers will alternately receive the conversion results after each interrupt event. The initial buffer used after BUFM is set is the lower group.

When BUFM is '0', the entire buffer is used for all conversion sequences.

Note:	When	the	BUFM	bit	is	set,	the	user
	should	l not	progran	n th	e S	MPI>	c bits	to a
	value	that	specifi	es	mo	re tl	han	(n/2)
	conve	rsions	s per int	erru	pt.			

The decision to use the split buffer feature will depend upon how much time is available to move the buffer contents after the interrupt, as determined by the application. If the application can quickly unload a full buffer within the time it takes to sample and convert one channel, the BUFM bit can be '0', and up to 16 conversions may be done per interrupt. The application will have one sample/convert time before the first buffer location is overwritten.

If the processor cannot unload the buffer within the sample and conversion time, the BUFM bit should be '1'. For example, if SMPI<4:0> = 00111, then eight conversions will be loaded into the lower half of the buffer, following which, an interrupt may occur. The next eight conversions will be loaded into the upper half of the buffer. The processor will, therefore, have the entire time between interrupts to move the eight conversions out of the buffer.

# 22.6.2.2 Buffer Fill Status

When the conversion result buffer is split (BUFM = 1), the BUFS Status bit (ADCON2L<7>) indicates which half of the buffer that the A/D Converter is currently writing. If BUFS = 0, the A/D Converter is filling the lower group and the user application should read conversion values from the upper group. If BUFS = 1, the situation is reversed, and the user application should read conversion values from the lower group.

### 22.6.2.3 Channel Indexed Mode

When BUFREGEN = 1, FIFO operation is disabled. In this Fill mode, the conversion result for each channel is written only to the buffer location that corresponds to that channel. For example, any conversions performed on AN0 are stored only in ADCBUF0. The same holds true for AN1 and ADCBUF1, and so on. Subsequent conversions on a particular channel that occur, prior to an interrupt, will result in any previous data in that location being overwritten.

Channel Indexed mode is particularly useful when used with the Threshold Detect feature, as this allows the user to easily test for a particular condition on a specific analog channel without creating an excess of CPU overhead. This is covered in more detail in **Section 22.7 "Threshold Detect Operation"**.

### 22.6.3 BUFFER DATA FORMATS

The results of each A/D conversion are 12 bits wide (optionally, 10 bits wide in some devices). To maintain data format compatibility, the result of each conversion is automatically converted to one of four selectable, 16bit formats. The FORM<1:0> bits (ADCON1H<1:0>) select the format. Figure 22-10 and Figure 22-11 show the data output formats that can be selected. Table 22-2 through Table 22-5 show the numerical equivalents for the various conversion result codes.

# 22.7 Threshold Detect Operation

Threshold Detect is a significant extension of the Auto-Scan feature offered in previous 10-bit A/D modules. In addition to being able to repeatedly sample a predefined sequence of analog channels, Threshold Detect allows the user to define match conditions based on the conversion results and generate an interrupt based on these conditions. During normal operation, this can potentially reduce the amount of CPU time spent on processing A/D interrupts. For low-power applications, this can allow the CPU to remain inactive for longer periods, waking only when specific analog conditions are met.

When selected by the user, Threshold Detect changes the operation of the A/D results buffer by making it a read/write array for both conversion results and comparison (threshold) values. It also brings into play the ADCHIT registers, which are used to indicate match conditions. Independently selectable comparison and buffer storage settings make a wide range of operating combinations possible.

# 22.7.1 OPERATING MODES

The operation of Threshold Detect is mostly controlled by the ADCON5H/L registers. The ASENA bit (ADCON5L<7>) controls overall operation of Threshold Detect; setting this bit enables the functionality.

As with Legacy Auto-Scan operation, the channels to be included are selected using the ADCSS1H/L, ADCSS0H/L registers. Setting a particular bit in either register includes the corresponding channel in an automatic sequential scan. One or more channels may be selected. After the channels have been selected, setting both the CSCNA and ASENA bits to enable a single scan of the designated channels. The scan itself is triggered by the trigger source programmed by the SSRC<3:0> bits.

**Note:** Legacy Auto-Scan (i.e., sequential scanning of analog channels on MUX A, without any comparison) is controlled by the CSCNA bit (ADCON2H<2>) and does not depend on the ASEN bit to function.

The LPENA bit (ADCON5H<6>) allows Threshold Detect to function with a low-power feature. By design, Threshold Detect can perform comparison operations when the device is in Sleep or Idle modes, waking the CPU when it generates an interrupt. Setting LPENA configures the device to return to low-power operation after the interrupt has been serviced.

The Compare Mode bits, CM<1:0> (ADCON5L<1:0>), select the type of comparison to be performed. Four types are available:

- The result of the current conversion is greater than a reference threshold
- The result of the current conversion is less than a reference threshold
- The result of the current conversion is between two predefined thresholds ("Inside Window")
- The result of the current conversion is outside of the predefined thresholds ("Outside Window")

The Write Mode bits, WM<1:0> (ADCON5L<3:2>), determine the disposition of the conversion. Three options are available:

- Discard the conversion after the comparison has been performed
- Store the conversion after the comparison has been performed
- Store the conversion without comparison (Legacy mode)

### 22.7.1.1 Buffer Operation And Comparisons

For Buffer Write modes that involve storing conversions (WM<1:0> = 0x), the BUFM and BUFREGEN bits control how the buffer functions (as a channel indexed, single FIFO or split FIFO buffer). However, when the compare and store option is selected (WM<1:0> = 01), using a FIFO mode may overwrite the buffers of other channels and cause unpredictable comparison results. For that reason, always use Channel Indexed Buffer mode (BUFREGEN = 1) when using the compare and store option.

### 22.7.1.2 Buffer Operation In Windowed Comparisons (Channel Mirroring)

The use of windowed comparisons changes the available options for the results buffer. To accommodate the storage of two threshold values, the buffer is automatically split into halves, similar to Split FIFO mode. Buffer addresses in each half are paired, with the lowest address in one buffer, matched to the buffer address in the upper half. (For example, in a 16-word buffer, ADC-BUF0 is paired with ADCBUF9, ADCBUF1 is paired with ADCBUF10, and so on.) This pairing is referred to as "channel mirroring". Mirroring can obviously be applied only to the lower A/ D channels; for most devices, this corresponds to the lower half of the external analog channels. This does not mean that those buffer locations cannot be used for other purposes. However, storing any other data in a particular buffer location, where channel mirroring is being used, may result in misleading comparison evaluations.

### 22.7.2 SETTING COMPARISON THRESHOLDS

The comparison thresholds for Threshold Detect are set by writing the desired values to an appropriate location in the A/D results buffer. This can only be done when the module is deactivated (ADCON1H<7> = 0).

The location of the threshold is determined by the comparison type. For simple greater than, and less than, comparisons, the value is written to the buffer location corresponding to the input channel to be monitored. For example, if AN0 is to be monitored for a voltage over a certain level, the ceiling threshold is stored in ADCBUF0.

The location of the thresholds for windowed comparisons are written to two addresses. The lower value is written to the address corresponding to the monitored channel. The upper value is stored in the corresponding mirrored address in the upper half of the buffer. To expand on the previous example, if the conversion on AN0 is to be a windowed comparison, the floor threshold is stored in ADCBUF0, while the ceiling threshold is stored in ADCBUF9.

# 22.7.3 COMPARE HIT REGISTERS

To determine if a particular event has occurred, the A/ D module uses two registers to record match events. These registers are referred to as the Compare Hit registers and are designated, ADCHIT1H/L and ADCHIT0H/L. The registers map their individual bits sequentially to each of the (up to) 32 analog channels. If a particular channel in a device is not implemented, the corresponding Compare Hit bit (CHHn) is not implemented.

Each bit serves as an event semaphore for its corresponding channel. When the programmed event occurs on that channel, the bit becomes set and stays set until it is cleared by the application. It is the user's responsibility to clear the bits after the application has evaluated them.

Depending on the event, more than one Compare Hit bit may be set. The significance of a set bit must be interpreted by the application in the context of the Compare mode selected. Particular examples are covered in Section 22.7.5 "Comparison Mode Examples".

### 22.7.4 THRESHOLD DETECT INTERRUPTS

The A/D module can generate an interrupt and set the ADIF flag based on Threshold Detect operation. This is based on completion of a Threshold Detect sequence and/or the occurrence of a valid comparison. When Threshold Detect is enabled (ASENA = 1), A/D module interrupt generation is governed by the ASINTMDx bits (ADCON5H<1:0>), superseding any configuration implemented by the SMPIx bits (ADCON2L<6:2>). For information on alternative interrupt settings, refer to Section 22.6.1 "Number of Conversions Per Interrupt".

The Threshold Detect interrupt is configured by the ASINTMD<1:0> bits (ADCON5H<1:0>). Options include interrupt after a scan sequence, interrupt after a scan sequence with a valid match, interrupt after a valid match (without waiting for the sequence to end) or no interrupt.

### 22.7.5 COMPARISON MODE EXAMPLES

The following examples show the effect of valid comparisons on the results buffer and the

Compare Hit registers. In each figure, changes within the registers are indicated in bold.

For the sake of simplicity, the examples assume a device with only 16 analog inputs. Devices with a greater number of channels, and thus, larger results buffers and two Compare Hit registers, will function in a similar fashion.

Note:	When using any comparison mode,
	always use channel indexed buffer
	storage (BUFREGEN = 1). Otherwise,
	the threshold values for other channels
	may be overwritten, resulting in
	unpredictable comparisons.

# 22.7.5.1 Simple Comparisons (Greater And Less Than Results)

When the Compare Mode bits, CM<1:0> (ADCON5L<1:0>), are programmed as '0x', the converter compares the sampled value to see if it is greater than (CM<1:0> = 01), or less than (CM<1:0> = 00), the threshold value in the buffer location. If the condition is met, both of the following occur:

- The Compare Hit bit (CHHn) for the corresponding channel is set.
- If the Write Mode bits, WM<1:0>
   (ADCON5L<3:2>), are programmed to '01', the
   converted value is written to the buffer, replacing
   the threshold value. If WM<1:0> = 10, the
   converted value is discarded.

The changes to the result buffer and the Compare Hit register are shown in Figure 22-13. Note that they are the same for both types of simple comparison.

### 22.7.5.2 Inside Window Comparison

When the Compare Mode bits, CM<1:0>, are programmed as '10', the converter compares the sampled value to see if it falls between the threshold values in the buffer and mirrored channel location. Since the value in the mirrored channel location is always the greater value of the two thresholds, the condition is met when:

#### Threshold 2 > Converted Value > Threshold 1

In this case, both of the following occur:

- The Compare Hit bit (CHHn) for the corresponding channel is set; the Compare Hit bit for the mirrored channel remains cleared.
- If the Write Mode bits, WM<1:0>
   (ADCON5L<3:2>), are programmed to '01', the
   converted value is written to the buffer, replacing
   the lower threshold value. If WM<1:0> = 10, the
   converted value is discarded.

The changes to the result buffer and the Compare Hit register are shown in Figure 22-14.

### 22.7.5.3 Outside Window Comparison

When the Compare Mode bits CM<1:0> are programmed as '11', the converter compares the sampled value to see if it falls outside of the threshold values in the buffer and mirrored channel location. Again, since the value in the mirrored channel location is always the greater value of the two thresholds, the condition is met when either:

Converted Value >Threshold 2

or

### Threshold 1 > Converted Value

In these cases, the following occurs:

- The Compare Hit bit (CHHn) for the corresponding channel is set.
- If the converted value is greater than Threshold 2, the CHHn bit for the mirrored channel is also set. If it is less than Threshold 1, the mirrored channel bit remains '0'.

- If the Write Mode bits, WM<1:0> (ADCON5L<3:2>), are programmed to '01':
  - If the converted value is above Threshold 2, the converted value is written to the mirrored channel address, replacing the upper threshold value.
  - If the converted value is below Threshold 1, the converted value is written to the channel address, replacing the lower threshold value.
- If WM<1:0> = 10, the converted value is discarded.

The changes to the result buffer and the Compare Hit register are shown in Figure 22-15 (over the upper threshold) and Figure 22-16 (under the lower threshold).

Note that when a Windowed Comparison mode is selected and channel mirroring is enabled, nothing prevents a conversion from another operation from being stored in the mirrored channel location. In the previous examples of windowed operation, if AN10 is included in a Threshold Detect operation, a conversion on AN10 might be tested against the upper threshold for AN2, stored in that location. This could result in the threshold value being overwritten and/or the CHH10 bit being set. For this reason, users must always carefully consider the allocation and use of the upper analog channels (both external and internal) when using Windowed Compare modes. Wherever possible, exclude the upper analog channels for Threshold Detect operations, and convert and test those channels in a separate routine.

### 22.8 Examples

#### 22.8.1 INITIALIZATION

Example 22-1 shows a simple initialization code example for the A/D module. Operation in Idle mode is disabled, output data is in unsigned fractional format, and AVDD and AVss are used for VR+ and VR-. The start of sampling, as well as the start of conversion (conversion trigger), are performed directly in software. Scanning of inputs is disabled and an interrupt occurs after every sample/convert sequence (one conversion result) with only one channel (AN0) being converted. The A/D conversion clock is TCY/2.

In this particular configuration, all 16 analog input pins are set up as analog inputs. It is important to note that with this A/D module, I/O pins are configured for analog or digital operation at the I/O port with the ANSn Analog Select registers. The use of these registers is described in detail in the I/O Port chapter of the specific device data sheet.

This example shows one method of controlling a sample/convert sequence by manually setting and clearing the SAMP bit (ADCON1L<1>). This method, among others, is more fully discussed in Section 22.4 "Controlling the Sampling Process" and Section 22.5 "Controlling the Conversion Process".

EXAMPLE 22-3: A/D INI	TIALIZATION CODE EXAMPLE
ADCON1H = $0x22;$	// Configure sample clock source
ADCON1L = $0 \times 00;$	// and conversion trigger mode.
	<pre>// Unsigned Fraction format (FORM&lt;1:0&gt;=10),</pre>
	<pre>// Manual conversion trigger (SSRC&lt;3:0&gt;=0000),</pre>
	// Manual start of sampling (ASAM=0),
	// S/H in Sample (SAMP = 1)
ADCON2H = 0;	// Configure A/D voltage reference
ADCON2L = 0;	// and buffer fill modes.
	<pre>// Vr+ and Vr- from AVdd and AVss(PVCFG&lt;1:0&gt;=00, NVCFG=0),</pre>
	// Inputs are not scanned,
	// Interrupt after every sample
ADCON3H = 0;	// Configure sample time = 1Tad,
ADCON3L = 0;	// A/D conversion clock as Tcy
ADCHSOH = 0;	// Configure input channels,
ADCHSOL = 0;	// S/H+ input is ANO,
	// S/H- input is Vr- (AVss).
ADCSSOL = 0;	// No inputs are scanned.
ADCSSOH = $0;$	// No inputs are scanned.
PIR1bits.ADIF = 0;	// Clear A/D conversion interrupt.
// Configure A/D inter	rupt priority bits (ADIP) here, if
// required. Default p	riority level is high.
PIE1bits.ADIE = 1;	// Enable A/D conversion interrupt
ADCON1Hbits.ADON = 1;	// Turn on A/D
ADCON1Lbits.SAMP = 1;	// Start sampling the input
Delay();	// Ensure the correct sampling time has elapsed
	// before starting conversion.
ADCON1Lbits.SAMP = 0;	// End A/D sampling and start conversion
// Example code for A/1	D ISR:
#pragma interrupt _ADC	lInterrupt
<pre>void _ADC1Interrupt(vo:</pre>	id)
{	
PIR1bits.ADIF = 0;	
}	

#### 22.8.2 CONVERSION SEQUENCE EXAMPLES

The following configuration examples show the A/D operation in different sampling and buffering configurations. In each example, setting the ASAM bit starts automatic sampling. A conversion trigger ends sampling and starts conversion.

#### 22.8.2.1 Sampling and Converting a Single Channel Multiple Times

In this case Figure 22-16, one A/D input, ANO, will be sampled and converted. The results are stored in the ADCBUFn buffer. This process repeats 16 times until the buffer is full and then the module generates an interrupt. The entire process will then repeat.

With the ALTS bit clear, only the MUX A inputs are active. The CH0SAx and CH0NAx bits are specified (AN0 - VR-) as the inputs to the Sample-and-Hold channel. All other input selection bits are unused.

## FIGURE 22-16: CONVERTING ONE CHANNEL 16 TIMES PER INTERRUPT

### EXAMPLE 22-4: CONVERTING A SINGLE CHANNEL 16 TIMES PER INTERRUPT

#### A/D Configuration:

- Select AN0 for S/H+ Input (CH0SA<4:0> = 00000)
- Select VR- for S/H- Input (CH0NA<2:0> = 000)
- Configure for No Input Scan (CSCNA = 0)
- Use Only MUX A for Sampling (ALTS = 0)
- Set AD1IF on Every 16th Sample (SMPI<4:0> = 01111)
- Configure Buffers for Single, 16-Word Results (BUFM = 0)

#### **Operational Sequence:**

- 1. Sample MUX A Input AN0; Convert and Write to Buffer 0h.
- 2. Sample MUX A Input AN0; Convert and Write to Buffer 1h.
- 3. Sample MUX A Input AN0; Convert and Write to Buffer 2h.
- 4. Sample MUX A Input AN0; Convert and Write to Buffer 3h.
- 5. Sample MUX A Input AN0; Convert and Write to Buffer 4h.
- 6. Sample MUX A Input AN0; Convert and Write to Buffer 5h.
- 7. Sample MUX A Input AN0; Convert and Write to Buffer 6h.
- 8. Sample MUX A Input AN0; Convert and Write to Buffer 7h.
- 9. Sample MUX A Input AN0; Convert and Write to Buffer 8h.
- 10. Sample MUX A Input AN0; Convert and Write to Buffer 9h.
- 11. Sample MUX A Input AN0; Convert and Write to Buffer Ah.
- 12. Sample MUX A Input AN0; Convert and Write to Buffer Bh.
- 13. Sample MUX A Input AN0; Convert and Write to Buffer Ch.
- 14. Sample MUX A Input AN0; Convert and Write to Buffer Dh.
- 15. Sample MUX A Input AN0; Convert and Write to Buffer Eh.
- 16. Sample MUX A Input AN0; Convert and Write to Buffer Fh.
- 17. Set AD1IF Flag (and generate interrupt, if enabled).
- 18. Repeat (1-16) After Return from Interrupt.

#### Results Stored in Buffer (after 2 cycles):

#### 22.8.2.2 A/D Conversions While Scanning Through All Analog Inputs

Figure 22-17 and Example 22-5 illustrate a typical setup, where all available analog input channels are sampled and converted. In this instance, 16 analog inputs are assumed. The set CSCNA bit specifies scanning of the A/D inputs to the S/H positive input.

Other conditions are similar to those located in Section Section 22.8.2.1 "Sampling and Converting a Single Channel Multiple Times".

Initially, the AN0 input is sampled and converted. The result is stored in the ADCBUFn buffer. Then, the AN1 input is sampled and converted. This process of scanning the inputs repeats 16 times, until the buffer is full, and then the module generates an interrupt. The entire process will then repeat.

Conversion Trigger ———			[ SAMP-►	; ; ;		Ts/	AMP->

### 22.8.3 USING DUAL BUFFERS

Figure 22-18 and Example 22-6 demonstrate using dual buffers and alternating the buffer fill.

Setting the BUFM bit enables dual buffers. In this example, an interrupt is generated after each sample. The BUFM setting does not affect other operational parameters. First, the conversion sequence starts filling the buffer at ADCBUF0. After the first interrupt occurs, the buffer begins to fill at ADCBUF8. The BUFS Status bit is toggled after each interrupt.

## FIGURE 22-18: CONVERTING A SINGLE CHANNEL, ONCE PER INTERRUPT, USING DUAL, 8-WORD BUFFERS

## EXAMPLE 22-6: CONVERTING A SINGLE CHANNEL, ONCE PER INTERRUPT, DUAL BUFFER MODE

#### A/D Configuration:

- Select AN3 for S/H+ Input (CH0SA<4:0> = 00011)
- Select VR- for S/H- Input (CH0NA<2:0> = 000)
- Configure for No Input Scan (CSCNA = 0)
- Use Only MUX A for Sampling (ALTS = 0)
- Set AD1IF on Every Sample (SMPI<4:0> = 00000)
- Configure Buffer as Dual, 8-Word Segments (BUFM = 1)

#### **Operational Sequence:**

- 1. Sample MUX A Input, AN3; Convert and Write to Buffer 0h.
- 2. Set AD1IF Flag (and generate interrupt, if enabled); Write Access Automatically Switches to Alternate Buffer.
- 3. Sample MUX A Input, AN3; Convert and Write to Buffer 8h.
- 4. Set AD1IF Flag (and generate interrupt, if enabled); Write Access Automatically Switches to Alternate Buffer.
- 5. Repeat (1-4).

#### 22.8.3.1 Using Alternating MUX A and MUX B Input Selections

Figure 22-19 and Example 22-7 demonstrate alternate sampling of the inputs assigned to MUX A and MUX B. Setting the ALTS bit enables alternating input selections. The first sample uses the MUX A inputs specified by the CH0SAx and CH0NAx bits. The next sample uses the MUX B inputs, specified by the CH0SBx and CH0NBx bits.

This example also demonstrates use of the dual, 8-word buffers. An interrupt occurs after every 8th sample, resulting in filling eight words into the buffer on each interrupt.

## 22.9 A/D Sampling Requirements

The Analog Input model of the 12-bit A/D Converter is shown in Figure 22-20. The total sampling time for the A/D is a function of the holding capacitor charge time.

For the A/D Converter to meet its specified accuracy, the charge holding capacitor (CHOLD) must be allowed to fully charge to the voltage level on the analog input pin. The source impedance (RS), the interconnect impedance (RIC) and the internal sampling switch (RSS) impedance combine to directly affect the time required to charge CHOLD. The combined impedance of the analog sources must, therefore, be small enough to fully charge the holding capacitor within the chosen sample time. To minimize the effects of pin leakage currents on the accuracy of the A/D Converter, the maximum recommended source impedance, RS, is 2.5 k. After the analog input channel is selected (changed), this sampling function must be completed prior to starting the conversion. The internal holding capacitor will be in a discharged state prior to each sample operation.

At least 1 TAD time period should be allowed between conversions for the sample time. For more details, see **Section 30.0 "Electrical Specifications"**.

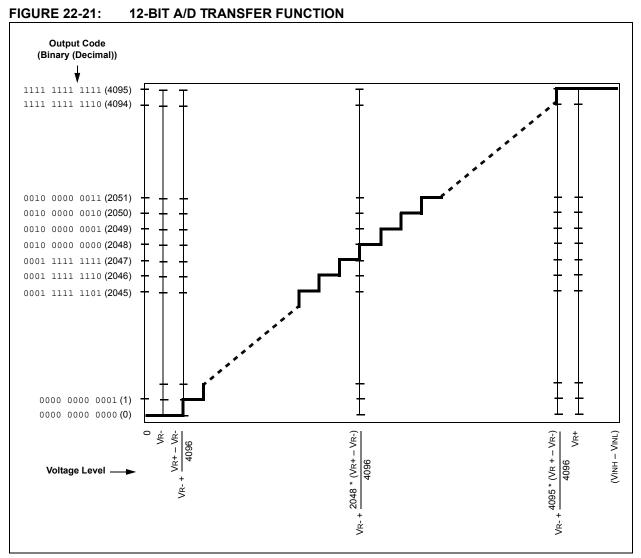

### 22.10 Transfer Functions

The transfer functions of the A/D Converter, in 12-bit and 10-bit resolution, are shown in Figure 22-21 and Figure 22-22, respectively. In both cases, the difference of the input voltages, (VINH - VINL), is compared to the reference, ((VR+) - (VR-)).

For the 12-bit transfer function:

- The first code transition occurs when the input voltage is ((VR+) (VR-))/4096 or 1.0 LSb.
- The '0000 0000 0001' code is centered at VR-+ (1.5 \* ((VR+) - (VR-)) / 4096).
- The '0010 0000 0000' code is centered at VREFL + (2048.5 \* ((VR+) (VR-)) /4096).
- An input voltage less than VR- + (((VR-) (VR-)) / 4096) converts as '0000 0000 0000'.
- An input voltage greater than (VR-) + (4096 ((VR+) - (VR-))/4096) converts as '1111 1111 1111'.

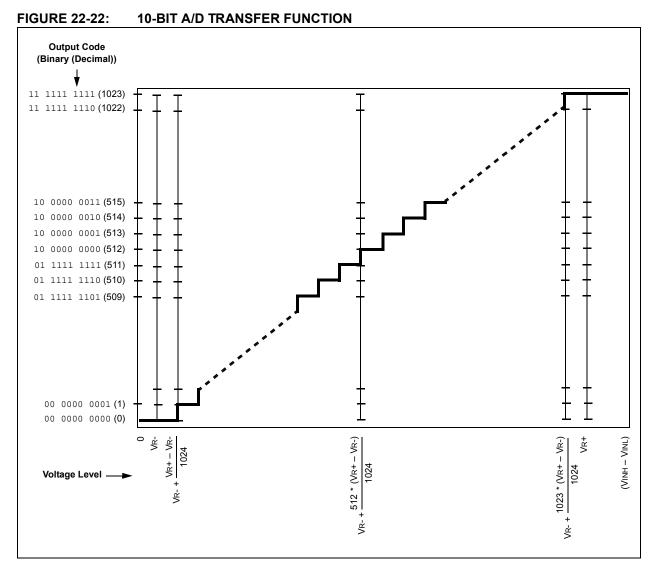

# PIC18F97J94 FAMILY

For the 10-bit transfer function (when 10-bit resolution is available):

- The first code transition occurs when the input voltage is ((VR+) (VR-))/1024 or 1.0 LSb.
- The '00 0000 0001' code is centered at VR- + (1.5 \* (((VR+) (VR-)) / 1024).
- The '10 0000 0000' code is centered at VREFL + (512.5 \* (((VR+) (VR-)) /1024).
- An input voltage less than VR- + (((VR-) (VR-)) / 1024) converts as '00 0000 0000'.
- An input voltage greater than (VR-) + ((1023 (VR+)) (VR-))/1024) converts as '11 1111 1111'.

# PIC18F97J94 FAMILY

### 22.11 Operation During Sleep and Idle Modes

Sleep and Idle modes are useful for minimizing conversion noise because the digital activity of the CPU, buses and other peripherals is minimized.

#### 22.11.1 CPU SLEEP MODE WITHOUT RC A/ D CLOCK

When the device enters Sleep mode, all clock sources to the module are shut down and stay at logic '0'.

If Sleep occurs in the middle of a conversion, the conversion is aborted unless the A/D is clocked from its internal RC clock generator. The converter will not resume a partially completed conversion on exiting from Sleep mode.

Register contents are not affected by the device entering or leaving Sleep mode.

# 22.11.2 CPU SLEEP MODE WITH RC A/D CLOCK

The A/D module can operate during Sleep mode if the A/D clock source is set to the internal A/D RC oscillator (ADRC = 1). This eliminates digital switching noise from the conversion. When the conversion is completed, the DONE bit will be set and the result is loaded into the A/D Result Buffer n, ADCBUFn.

If the A/D interrupt is enabled (ADIE = 1), the device will wake-up from Sleep when the A/D interrupt occurs. Program execution will resume at the A/D Interrupt Service Routine (ISR). After the ISR completes execution will continue from the instruction after the SLEEP instruction that placed the device in Sleep mode.

If the A/D interrupt is not enabled, the A/D module will then be turned off, although the ADON bit will remain set. To minimize the effects of digital noise on the A/D module operation, the user should select a conversion trigger source that ensures the A/D conversion will take place in Sleep mode. The automatic conversion trigger option can be used for sampling and conversion in Sleep (SSRC<3:0> = 0111). To use the automatic conversion option, the ADON bit should be set in the instruction prior to the SLEEP instruction.

Note:	For the A/D module to operate in Sleep,
	the A/D clock source must be set to RC
	(ADRC = 1).

## 22.11.3 A/D OPERATION DURING CPU IDLE MODE

The module will continue normal operation when the device enters Idle mode. If the A/D interrupt is enabled (ADIE = 1), the device will wake-up from Idle mode when the A/D interrupt occurs. If the respective global interrupt enable bit(s) are also set, program execution will resume at the A/D Interrupt Service Routine (ISR). After the ISR completes, execution will continue from the instruction after the SLEEP instruction that placed the device in Idle mode.

#### 22.11.4 PERIPHERAL MODULE DISABLE (PMD) REGISTER

The Peripheral Module Disable (PMD) registers provide a method to disable the A/D module by stopping all clock sources supplied to that module. When a peripheral is disabled via the appropriate PMDx control bit, the peripheral is in a minimum power consumption state. The control and STATUS registers associated with the peripheral will also be disabled, so writes to those registers will have no effect and read values will be invalid. The A/D module is enabled only when the ADCMD bit in the PMD3 register is cleared.

## 22.12 Design Tips

#### Question 1: How can I optimize the system performance of the A/D Converter?

**Answer:** There are three main things to consider in optimizing A/D performance:

 Make sure you are meeting all of the timing specifications. If you are turning the module off and on, there is a minimum delay you must wait before taking a sample. If you are changing input channels, there is a minimum delay you must wait for this as well, and finally, there is TAD, which is the time selected for each bit conversion. This is selected in AD1CON3 and should be within a certain range, as specified in Section 30.0 "Electrical Specifications". If TAD is too short, the result may not be fully converted before the con- version is terminated, and if TAD is made too long, the voltage on the sampling capacitor can decay before the conversion is complete. These timing specifications are provided in the "Electrical Characteristics" section of the device data sheets.

- 2. Often, the source impedance of the analog signal is high (greater than 2.5 k $\Omega$ ), so the current drawn from the source by leakage, and to charge the sample capacitor, can affect accuracy. If the input signal does not change too quickly, try putting a 0.1 uF capacitor on the analog input. This capacitor will charge to the analog voltage being sampled and supply the instantaneous current needed to charge the internal holding capacitor.
- Put the device into Sleep mode before the start of the A/D conversion. The RC clock source selection is required for conversions in Sleep mode. This technique increases accuracy, because digital noise from the CPU and other peripherals is minimized.

#### Question 2: Do you know of a good reference on A/ D Converters?

**Answer:** A good reference for understanding A/D conversions is the "Analog-Digital Conversion

Handbook third edition, published by Prentice Hall (ISBN 0-13-03-2848-0).

#### Question 3: My combination of channels/samples and samples/interrupt is greater than the size of the buffer. What will happen to the buffer?

**Answer:** This configuration is not recommended. The buffer will contain unknown results.

## 22.13 Related Application Notes

This section lists application notes that are related to this section of the data sheet. These application notes may not be written specifically for the PIC18F device family, but the concepts are pertinent and could be used with modification and possible limitations. The current application notes related to the 12-Bit A/D Converter with Threshold Detect module are:

AN546, Using the Analog-to-Digital (A/D) Converter (DS00546)

AN557, Four-Channel Digital Voltmeter with Display and Keyboard (DS00557)

## 23.0 COMPARATOR MODULE

The analog comparator module contains three comparators that can be independently configured in a variety of ways. The inputs can be selected from the analog inputs and two internal voltage references. The digital outputs are available at the pin level, via PPS-Lite, and can also be read through the control register. Multiple output and interrupt event generations are also available. A generic single comparator from the module is shown in Figure 23-1.

Key features of the module includes:

- Independent comparator control
- Programmable input configuration
- · Output to both pin and register levels
- · Programmable output polarity
- Independent interrupt generation for each comparator with configurable interrupt-on-change

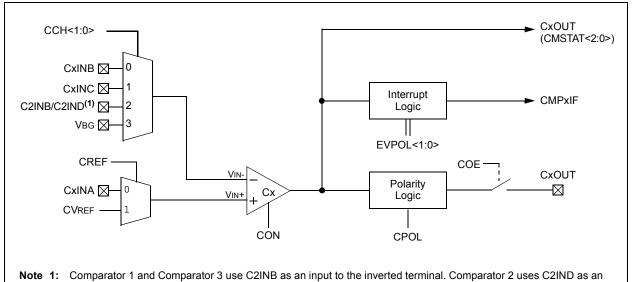

input to the inverted terminal.

## 23.1 Registers

The CMxCON registers (CM1CON, CM2CON and CM3CON) select the input and output configuration for each comparator, as well as the settings for interrupt generation (see Register 23-1).

The CMSTAT register (Register 23-2) provides the output results of the comparators. The bits in this register are read-only.

CPOL = 1 (inverted polarity):

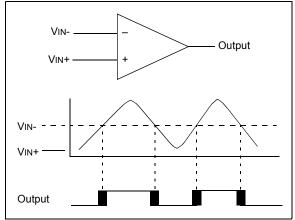

1 = Comparator x's VIN+ < VIN-

0 = Comparator x's VIN + > VIN

## 23.2 Comparator Operation

A single comparator is shown in Figure 23-2, along with the relationship between the analog input levels and the digital output. When the analog input at VIN+ is less than the analog input, VIN-, the output of the comparator is a digital low level. When the analog input at VIN+ is greater than the analog input, VIN-, the output of the comparator is a digital high level. The shaded areas of the output of the comparator in Figure 23-2 represent the uncertainty due to input offsets and response time.

FIGURE 23-2: SINGLE COMPARATOR

## 23.3 Comparator Response Time

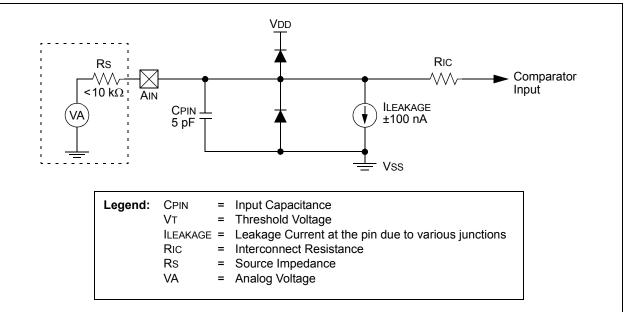

Response time is the minimum time, after selecting a new reference voltage or input source, before the comparator output has a valid level. The response time of the comparator differs from the settling time of the voltage reference. Therefore, both of these times must be considered when determining the total response to a comparator input change. Otherwise, the maximum delay of the comparators should be used (see **Section 30.0 "Electrical Specifications"**).

## 23.4 Analog Input Connection Considerations

A simplified circuit for an analog input is shown in Figure 23-3. Since the analog pins are connected to a digital output, they have reverse biased diodes to VDD and VSS. The analog input, therefore, must be between VSS and VDD. If the input voltage deviates from this range by more than 0.6V in either direction, one of the diodes is forward biased and a latch-up condition may occur.

A maximum source impedance of  $10 \text{ k}\Omega$  is recommended for the analog sources. Any external component connected to an analog input pin, such as a capacitor or a Zener diode, should have very little leakage current.

# 23.5 Comparator Control and Configuration

Each comparator has up to eight possible combinations of inputs: up to four external analog inputs and one of two internal voltage references.

All of the comparators allow a selection of the signal from pin, CXINA, or the voltage from the Comparator Reference (CVREF) on the non-inverting channel. This is compared to either CXINB, CXINC, C2IND or the microcontroller's fixed internal reference voltage (VBG, 1.2V nominal) on the inverting channel. The comparator inputs and outputs are tied to fixed I/O pins, defined in Table 23-1. The available comparator configurations and their corresponding bit settings are shown in Figure 23-4.

TABLE 23-1: COMPARATOR INPUTS AND OUTPUTS

Comparator	Input or Output	I/O Pin <sup>(†)</sup>

	C3OUT	RPn <sup>(1)</sup>

† The I/O pin is dependent on package type.

Note 1: These pins are remappable I/Os.

2: These pins are not available on 64-pin devices.

## 23.5.1 COMPARATOR ENABLE AND INPUT SELECTION

Setting the CON bit of the CMxCON register (CMxCON<7>) enables the comparator for operation. Clearing the CON bit disables the comparator, resulting in minimum current consumption.

The CCH<1:0> bits in the CMxCON register (CMxCON<1:0>) direct either one of three analog input pins, or the Internal Reference Voltage (VBG), to the comparator, VIN-. Depending on the comparator operating mode, either an external or internal voltage reference may be used.

The analog signal present at VIN- is compared to the signal at VIN+ and the digital output of the comparator is adjusted accordingly.

The external reference is used when CREF = 0 (CMxCON<2>) and VIN+ is connected to the CxINA pin. When external voltage references are used, the comparator module can be configured to have the reference sources externally. The reference signal must be between VSS and VDD and can be applied to either pin of the comparator.

The comparator module also allows the selection of an internally generated voltage reference from the Comparator Voltage Reference (CVREF) module. This module is described in more detail in **Section 24.0** "Comparator **Voltage Reference Module**". The reference from the comparator voltage reference module is only available when CREF = 1. In this mode, the internal voltage reference is applied to the comparator's VIN+ pin.

Note: The comparator input pin selected by CCH<1:0> must be configured as an input by setting both the corresponding TRISx bit and the corresponding ANSELx bit in the ANCONx register.

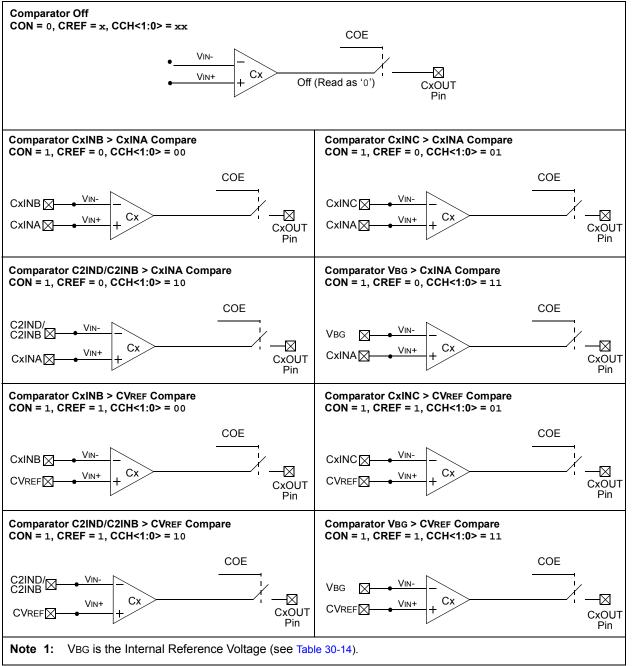

#### 23.5.2 COMPARATOR ENABLE AND OUTPUT SELECTION

The comparator outputs are read through the CMSTAT register. The CMSTAT<0> bit reads the Comparator 1 output, CMSTAT<2> reads the Comparator 2 output and the CMSTAT<3> bit reads the Comparator 3 output These bits are read-only.

The comparator outputs may also be directly output to the RPn I/O pins by setting the COE bit (CMxCON<6>). When enabled, multiplexers in the output path of the pins switch to the output of the comparator. While in this mode, the respective TRISx bits still function as the digital output enable bits for the RPn I/O pins. By default, the comparator's output is at logic high whenever the voltage on VIN+ is greater than on VIN-. The polarity of the comparator outputs can be inverted using the CPOL bit (CMxCON<5>).

The uncertainty of each of the comparators is related to the input offset voltage and the response time given in the specifications, as discussed in **Section 23.2 "Comparator Operation"**.

## 23.6 Comparator Interrupts

The comparator interrupt flag is set whenever any of the following occurs:

- · Low-to-high transition of the comparator output
- High-to-low transition of the comparator output
- Any change in the comparator output

The comparator interrupt selection is done by the EVPOL<1:0> bits in the CMxCON register (CMxCON<4:3>).

In order to provide maximum flexibility, the output of the comparator may be inverted using the CPOL bit in the CMxCON register (CMxCON<5>). This is functionally identical to reversing the inverting and non-inverting inputs of the comparator for a particular mode.

An interrupt is generated on the low-to-high or high-tolow transition of the comparator output. This mode of interrupt generation is dependent on EVPOL<1:0> in the CMxCON register. When EVPOL<1:0> = 01 or 10, the interrupt is generated on a low-to-high or high-tolow transition of the comparator output. Once the interrupt is generated, it is required to clear the interrupt flag by software. When EVPOL<1:0> = 11, the comparator interrupt flag is set whenever there is a change in the output value of either comparator. Software will need to maintain information about the status of the output bits, as read from CMSTAT<2:0>, to determine the actual change that occurred.

The CMPxIF<2:0> (PIR6<2:0>) bits are the Comparator Interrupt Flags. The CMPxIF bits must be reset by clearing them. Since it is also possible to write a '1' to this register, a simulated interrupt may be initiated. Table 23-2 shows the interrupt generation with respect to comparator input voltages and EVPOL bit settings.

Both the CMPxIE bits (PIE6<2:0>) and the PEIE bit (INTCON<6>) must be set to enable the interrupt. In addition, the GIE bit (INTCON<7>) must also be set. If any of these bits are clear, the interrupt is not enabled, though the CMPxIF bits will still be set if an interrupt condition occurs.

A simplified diagram of the interrupt section is shown in Figure 23-3.

**Note:** CMPxIF will not be set when EVPOL<1:0> = 00.

CPOL	EVPOL<1:0>	Comparator Input Change	CxOUT Transition	Interrupt Generated
	0.0	VIN+ > VIN-	Low-to-High	No
	00	VIN+ < VIN-	High-to-Low	No
	0.1	VIN+ > VIN-	Low-to-High	Yes
2	01	Vin+ < Vin-	High-to-Low	No
0	1.0	VIN+ > VIN-	Low-to-High	No
	10	VIN+ < VIN-	High-to-Low	Yes
	11	VIN+ > VIN-	Low-to-High	Yes
		Vin+ < Vin-	High-to-Low	Yes
	00	VIN+ > VIN-	High-to-Low	No
		Vin+ < Vin-	Low-to-High	No
		VIN+ > VIN-	High-to-Low	No
-	01	Vin+ < Vin-	Low-to-High	Yes
1	1.0	VIN+ > VIN-	High-to-Low	Yes
	10	VIN+ < VIN-	Low-to-High	No
	11	VIN+ > VIN-	High-to-Low	Yes
	11	VIN+ < VIN-	Low-to-High	Yes

 TABLE 23-2:
 COMPARATOR INTERRUPT GENERATION

## 23.7 Comparator Operation During Sleep

When a comparator is active and the device is placed in Sleep mode, the comparator remains active and the interrupt is functional, if enabled. This interrupt will wake-up the device from Sleep mode when enabled. Each operational comparator will consume additional current.

To minimize power consumption while in Sleep mode, turn off the comparators (CON = 0) before entering Sleep. If the device wakes up from Sleep, the contents of the CMxCON register are not affected.

## 23.8 Effects of a Reset

A device Reset forces the CMxCON registers to their Reset state. This forces both comparators and the voltage reference to the OFF state.

## 24.0 COMPARATOR VOLTAGE REFERENCE MODULE

The comparator voltage reference is a 32-tap resistor ladder network that provides a selectable reference voltage. Although its primary purpose is to provide a reference for the analog comparators, it may also be used independently of them.

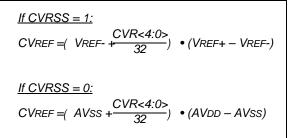

A block diagram of the module is shown in Figure 24-1. The resistor ladder is segmented to provide a range of CVREF values and has a power-down function to conserve power when the reference is not being used. The module's supply reference can be provided from either device VDD/VSS or an external voltage reference.

## 24.1 Configuring the Comparator Voltage Reference

The comparator voltage reference module is controlled through the CVRCONH register (Register 24-1). The comparator voltage reference provides a range of output voltage with 32 levels.

The CVR<4:0> selection bits (CVRCONH<4:0>) offer a range of output voltages. Equation 24-1 shows how the comparator voltage reference is computed.

#### EQUATION 24-1:

The comparator voltage reference supply can come from either VDD and VSS, or the external VREF+ and VREF- that are multiplexed with RA3 and RA2. The voltage source is selected by the CVRPSS<1:0> bits (CVRCONL<5:4>).

The settling time of the comparator voltage reference must be considered when changing the CVREF output (see Table 30-13 in Section 30.0 "Electrical Specifications").

	00 = AVss

## FIGURE 24-1: COMPARATOR VOLTAGE REFERENCE BLOCK DIAGRAM

## 24.2 Voltage Reference Accuracy/Error

The full range of voltage reference cannot be realized due to the construction of the module. The transistors on the top and bottom of the resistor ladder network (Figure 24-1) keep CVREF from approaching the reference source rails. The voltage reference is derived from the reference source; therefore, the CVREF output changes with fluctuations in that source. The tested absolute accuracy of the voltage reference can be found in Section 30.0 "Electrical Specifications".

## 24.3 Operation During Sleep

When the device wakes up from Sleep through an interrupt or a Watchdog Timer time-out, the contents of the CVRCON register are not affected. To minimize current consumption in Sleep mode, the voltage reference should be disabled.

## 24.4 Effects of a Reset

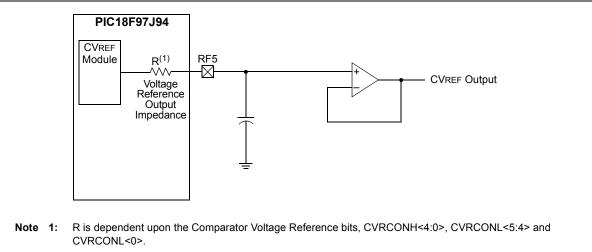

A device Reset disables the voltage reference by clearing bit, CVREN (CVRCONL<7>). This Reset also disconnects the reference from the RF5 pin by clearing bit, CVROE (CVRCONL<6>).

## 24.5 Connection Considerations

The voltage reference module operates independently of the comparator module. The output of the reference generator may be connected to the RA0 pin if the CVROE bit is set. Enabling the voltage reference output onto RA0, when it is configured as a digital input, will increase current consumption. Connecting RA0 as a digital output with CVRSS enabled will also increase current consumption.

The RA0 pin can be used as a simple D/A output with limited drive capability. Due to the limited current drive capability, a buffer must be used on the voltage reference output for external connections to VREF. Figure 24-2 shows an example buffering technique.

#### FIGURE 24-2: COMPARATOR VOLTAGE REFERENCE OUTPUT BUFFER EXAMPLE

## 25.0 HIGH/LOW-VOLTAGE DETECT (HLVD)

The PIC18FXXJ94 of devices has a High/Low-Voltage Detect module (HLVD). This is a programmable circuit that sets both a device voltage trip point and the direction of change from that point. If the device experiences an excursion past the trip point in that direction, an interrupt flag is set. If the interrupt is enabled, the program execution branches to the interrupt vector address and the software responds to the interrupt.

The High/Low-Voltage Detect Control register (Register 25-1) completely controls the operation of the HLVD module. This allows the circuitry to be "turned off" by the user under software control, which minimizes the current consumption for the device.

The module's block diagram is shown in Figure 25-1.

#### REGISTER 25-1: HLVDCON: HIGH/LOW-VOLTAGE DETECT CONTROL REGISTER

R/W-0	R-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

	1110 = Maximum setting
	0100 = Minimum setting
	o too mining odding
Note 1:	For the electrical specifications, see Parameter D420.

The module is enabled by setting the HLVDEN bit (HLVDCON<4>). Each time the HLVD module is enabled, the circuitry requires some time to stabilize. The IRVST bit (HLVDCON<5>) is a read-only bit used to indicate when the circuit is stable. The module can only generate an interrupt after the circuit is stable and IRVST is set.

The VDIRMAG bit (HLVDCON<7>) determines the overall operation of the module. When VDIRMAG is cleared, the module monitors for drops in VDD below a predetermined set point. When the bit is set, the module monitors for rises in VDD above the set point.

## 25.1 Operation

When the HLVD module is enabled, a comparator uses an internally generated reference voltage as the set point. The set point is compared with the trip point, where each node in the resistor divider represents a trip point voltage. The "trip point" voltage is the voltage level at which the device detects a high or low-voltage event, depending on the configuration of the module.

When the supply voltage is equal to the trip point, the voltage tapped off of the resistor array is equal to the internal reference voltage generated by the voltage reference module. The comparator then generates an interrupt signal by setting the HLVDIF bit.

The trip point voltage is software programmable to any of 16 values. The trip point is selected by programming the HLVDL<3:0> bits (HLVDCON<3:0>).

The HLVD module has an additional feature that allows the user to supply the trip voltage to the module from an external source. This mode is enabled when bits, HLVDL<3:0>, are set to '1111'. In this state, the comparator input is multiplexed from the external input pin, HLVDIN. This gives users the flexibility of configuring the High/Low-Voltage Detect interrupt to occur at any voltage in the valid operating range.

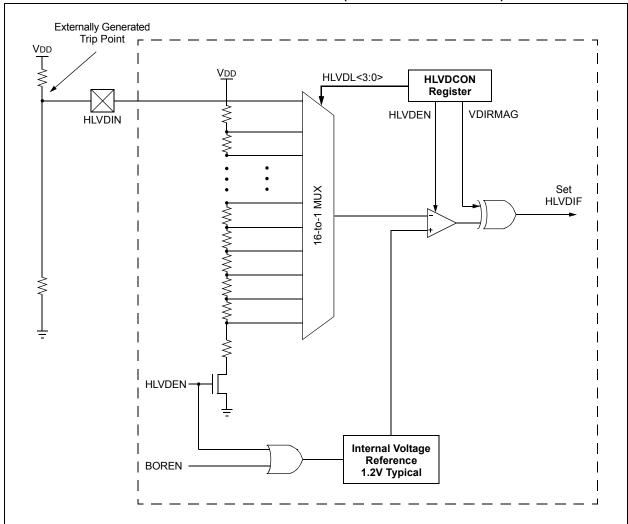

FIGURE 25-1: HLVD MODULE BLOCK DIAGRAM (WITH EXTERNAL INPUT)

## 25.2 HLVD Setup

To set up the HLVD module:

- 1. Select the desired HLVD trip point by writing the value to the HLVDL<3:0> bits.
- 2. Set the VDIRMAG bit to detect high voltage (VDIRMAG = 1) or low voltage (VDIRMAG = 0).
- 3. Enable the HLVD module by setting the HLVDEN bit.
- 4. Clear the HLVD interrupt flag (PIR2<2>), which may have been set from a previous interrupt.
- 5. If interrupts are desired, enable the HLVD interrupt by setting the HLVDIE and GIE bits (PIE2<2> and INTCON<7>, respectively).

An interrupt will not be generated until the IRVST bit is set.

Note:	Before changing any module settings
	(VDIRMAG, HLVDL<3:0>), first disable the
	module (HLVDEN = 0), make the changes
	and re-enable the module. This prevents
	the generation of false HLVD events.

## 25.3 Current Consumption

When the module is enabled, the HLVD comparator and voltage divider are enabled and consume static current.

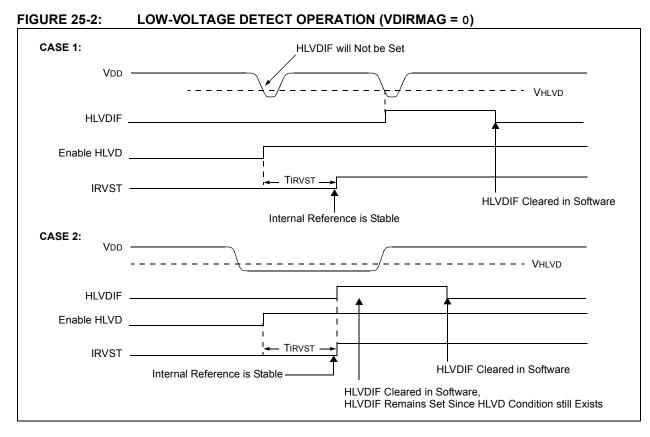

Depending on the application, the HLVD module does not need to operate constantly. To reduce current requirements, the HLVD circuitry may only need to be enabled for short periods where the voltage is checked. After such a check, the module could be disabled.

## 25.4 HLVD Start-up Time

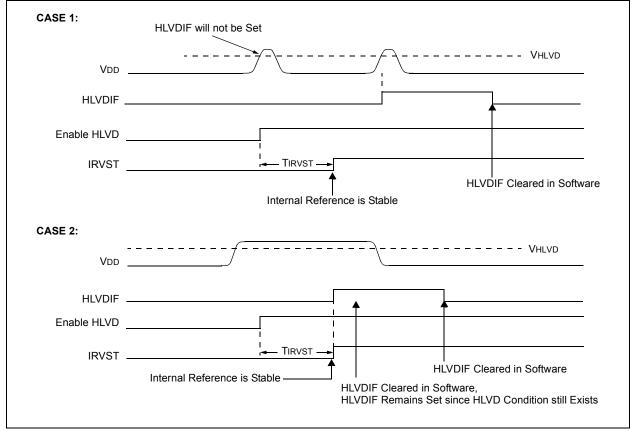

The internal reference voltage of the HLVD module, specified in electrical specification, Parameter **37** (Section 30.0 "Electrical Specifications"), may be used by other internal circuitry, such as the programmable Brown-out Reset. If the HLVD or other circuits using the voltage reference are disabled to lower the device's current consumption, the reference voltage circuit will require time to become stable before a low or high-voltage condition can be reliably detected. This start-up time, TIRVST, is an interval that is independent of device clock speed. It is specified in electrical specification, Parameter **37** (Table 30-26).

The HLVD interrupt flag is not enabled until TIRVST has expired and a stable reference voltage is reached. For this reason, brief excursions beyond the set point may not be detected during this interval (see Figure 25-2 or Figure 25-3).

# PIC18F97J94 FAMILY

#### FIGURE 25-3: HIGH-VOLTAGE DETECT OPERATION (VDIRMAG = 1)

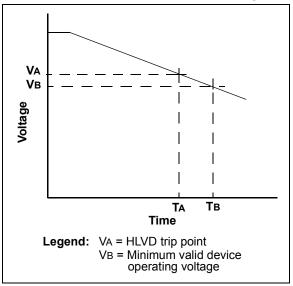

## 25.5 Applications

In many applications, it is desirable to detect a drop below, or rise above, a particular voltage threshold. For example, the HLVD module could be periodically enabled to detect Universal Serial Bus (USB) attach or detach. This assumes the device is powered by a lower voltage source than the USB when detached. An attach would indicate a high-voltage detect from, for example, 3.3V to 5V (the voltage on USB) and vice versa for a detach. This feature could save a design a few extra components and an attach signal (input pin).

For general battery applications, Figure 25-4 shows a possible voltage curve. Over time, the device voltage decreases. When the device voltage reaches voltage, VA, the HLVD logic generates an interrupt at time, TA. The interrupt could cause the execution of an ISR, which would allow the application to perform "housekeeping tasks" and a controlled shutdown, before the device voltage exits the valid operating range at TB. This would give the application a time window, represented by the difference between TA and TB, to safely exit.

## FIGURE 25-4: TYPICAL LOW-VOLTAGE DETECT APPLICATION

## 25.6 Operation During Sleep

When enabled, the HLVD circuitry continues to operate during Sleep. If the device voltage crosses the trip point, the HLVDIF bit will be set and the device will wake-up from Sleep. Device execution will continue from the interrupt vector address if interrupts have been globally enabled.

## 25.7 Effects of a Reset

A device Reset forces all registers to their Reset state. This forces the HLVD module to be turned off.

## 26.0 CHARGE TIME MEASUREMENT UNIT (CTMU)

The Charge Time Measurement Unit (CTMU) is a flexible analog module that provides accurate differential time measurement between pulse sources, as well as asynchronous pulse generation. By working with other on-chip analog modules, the CTMU can precisely measure time, capacitance and relative changes in capacitance or generate output pulses with a specific time delay. The CTMU is ideal for interfacing with capacitive-based sensors.

The module includes these key features:

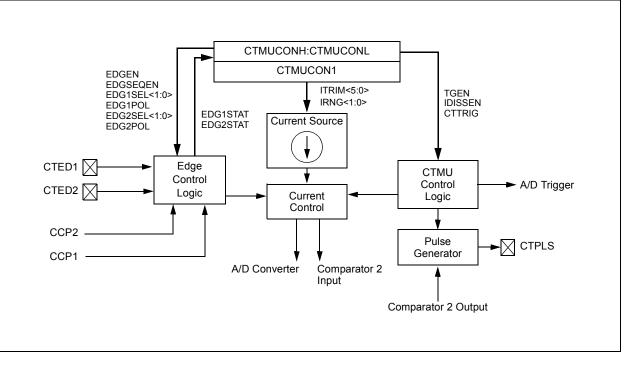

- Up to 24 channels available for capacitive or time measurement input
- Low-cost temperature measurement using on-chip diode channel
- On-chip precision current source
- · Sixteen-edge input trigger sources
- · Polarity control for each edge source
- Provides a trigger for the A/D Converter

- Control of edge sequence
- · Control of response to edges
- · Time measurement resolution of 1 nanosecond
- · High-precision time measurement
- Time delay of external or internal signal asynchronous to system clock
- Accurate current source suitable for capacitive measurement

The CTMU works in conjunction with the A/D Converter to provide up to 24 channels for time or charge measurement, depending on the specific device and the number of A/D channels available. When configured for time delay, the CTMU is connected to one of the analog comparators. The level-sensitive input edge sources can be selected from four sources: two external inputs or the CCP1/CCP2 Special Event Triggers.

The CTMU special event can trigger the Analog-to-Digital Converter module.

Figure 26-1 provides a block diagram of the CTMU.

## FIGURE 26-1: CTMU BLOCK DIAGRAM

## 26.1 CTMU Registers

The control registers for the CTMU are:

- CTMUCON1
- CTMUCON2
- CTMUCON3
- CTMUCON4

The CTMUCON1 and CTMUCON3 registers (Register 26-1 and Register 26-3) contain control bits for configuring the CTMU module edge source selection, edge source polarity selection, edge sequencing, A/D trigger, analog circuit capacitor discharge and enables. The CTMUCON2 register (Register 26-2) has bits for selecting the current source range and current source trim.

## 26.2 CTMU Operation

The CTMU works by using a fixed current source to charge a circuit. The type of circuit depends on the type of measurement being made.

In the case of charge measurement, the current is fixed and the amount of time the current is applied to the circuit is fixed. The amount of voltage read by the A/D becomes a measurement of the circuit's capacitance.

In the case of time measurement, the current, as well as the capacitance of the circuit, is fixed. In this case, the voltage read by the A/D is representative of the amount of time elapsed from the time the current source starts and stops charging the circuit.

If the CTMU is being used as a time delay, both capacitance and current source are fixed, as well as the voltage supplied to the comparator circuit. The delay of a signal is determined by the amount of time it takes the voltage to charge to the comparator threshold voltage.

## 26.2.1 THEORY OF OPERATION

The operation of the CTMU is based on the equation for charge:

$$I = C \bullet \frac{dV}{dT}$$

More simply, the amount of charge measured in coulombs in a circuit is defined as current in amperes (I), multiplied by the amount of time in seconds that the current flows (t). Charge is also defined as the capacitance in farads (C), multiplied by the voltage of the circuit (V). It follows that:

 $I \bullet t = C \bullet V$ 

The CTMU module provides a constant, known current source. The A/D Converter is used to measure (V) in the equation, leaving two unknowns: capacitance (C) and time (t). The above equation can be used to calculate capacitance or time, by either the relationship using the known fixed capacitance of the circuit:

 $t = (C \bullet V)/I$ 

or by:

$$C = (I \bullet t)/V$$

using a fixed time that the current source is applied to the circuit.

## 26.2.2 CURRENT SOURCE

At the heart of the CTMU is a precision current source, designed to provide a constant reference for measurements. The level of current is user-selectable across three ranges, or a total of two orders of magnitude, with the ability to trim the output in  $\pm 2\%$  increments (nominal). The current range is selected by the IRNG<1:0> bits (CTMUCON1<1:0>), with a value of '01' representing the lowest range.

Current trim is provided by the ITRIM<5:0> bits (CTMUCON1<7:2>). These six bits allow trimming of the current source, in steps of approximately 2% per step. Half of the range adjusts the current source positively and the other half reduces the current source. A value of '000000' is the neutral position (no change). A value of '100001' is the maximum negative adjustment (approximately -62%) and '011111' is the maximum positive adjustment (approximately +62%).

## 26.2.3 EDGE SELECTION AND CONTROL

CTMU measurements are controlled by edge events occurring on the module's two input channels. Each channel, referred to as Edge 1 and Edge 2, can be configured to receive input pulses from one of the edge input pins (CTED1 and CTED2) or CCPx Special Event Triggers (CCP1 and CCP2). The input channels are level-sensitive, responding to the instantaneous level on the channel rather than a transition between levels. The inputs are selected using the EDG1SELx (CTMUCON2<5:2>) and EDG2SELx (CTMUCON3<5:2>) bit pairs.

In addition to source, each channel can be configured for event polarity using the EDGE2POL (CTMU-CON2<6>) and EDGE1POL (CTMUCON3<6> bits. The input channels can also be filtered for an edge event sequence (Edge 1 occurring before Edge 2) by setting the EDGSEQEN bit (CTMUCON<2>).

## 26.2.4 EDGE STATUS

The CTMUCON3 register also contains two Edge Status bits: EDG2STAT and EDG1STAT (CTMUCON3<1:0>). Their primary function is to show if an edge response has occurred on the corresponding channel. The CTMU automatically sets a particular bit when an edge response is detected on its channel. The level-sensitive nature of the input channels also means that the Status bits become set immediately if the channel's configuration is changed and matches the channel's current state.

The module uses the Edge Status bits to control the current source output to external analog modules (such as the A/D Converter). Current is only supplied to external modules when only one (not both) of the Status bits is set. Current is shut off when both bits are either set or cleared. This allows the CTMU to measure current only during the interval between edges. After both Status bits are set, it is necessary to clear them before another measurement is taken. Both bits should be cleared simultaneously, if possible, to avoid re-enabling the CTMU current source.

In addition to being set by the CTMU hardware, the Edge Status bits can also be set by software. This permits a user application to manually enable or disable the current source. Setting either (but not both) of the bits enables the current source. Setting or clearing both bits at once disables the source.

## 26.2.5 INTERRUPTS

The CTMU sets its interrupt flag (PIR3<3>) whenever the current source is enabled, then disabled. An interrupt is generated only if the corresponding interrupt enable bit (PIE3<3>) is also set. If edge sequencing is not enabled (i.e., Edge 1 must occur before Edge 2), it is necessary to monitor the Edge Status bits, and determine which edge occurred last and caused the interrupt.

## 26.3 CTMU Module Initialization

The following sequence is a general guideline used to initialize the CTMU module:

- 1. Select the current source range using the IRNGx bits (CTMUCON1<1:0>).
- 2. Adjust the current source trim using the ITRIMx bits (CTMUCON1<7:2>).
- Configure the edge input sources for Edge 1 and Edge 2 by setting the EDG1SELx and EDG2SELx bits (CTMUCON3<5:2> and CTMU-CON2<5:2>, respectively).
- Configure the input polarities for the edge inputs using the EDG1POL and EDG2POL bits (CTMUCON3<6> and CTMUCON2<6>).
   The default configuration is for negative edge polarity (high-to-low transitions).
- Enable edge sequencing using the EDGSEQEN bit (CTMUCON<2>).

By default, edge sequencing is disabled.

 Select the operating mode (Measurement or Time Delay) with the TGEN bit (CTMUCON<4>).

The default mode is Time/Capacitance Measurement mode.

 Configure the module to automatically trigger an A/D conversion when the second edge event has occurred using the CTTRIG bit (CTMUCON<0>).

The conversion trigger is disabled by default.

- 8. Discharge the connected circuit by setting the IDISSEN bit (CTMUCON<1>).
- 9. After waiting a sufficient time for the circuit to discharge, clear the IDISSEN bit.
- 10. Disable the module by clearing the CTMUEN bit (CTMUCON<7>).
- Clear the Edge Status bits, EDG2STAT and EDG1STAT (CTMUCON3<1:0>).
   Both bits should be cleared simultaneously, if possible, to avoid re-enabling the CTMU current source.
- 12. Enable both edge inputs by setting the EDGEN bit (CTMUCON<3>).
- 13. Enable the module by setting the CTMUEN bit.

Depending on the type of measurement or pulse generation being performed, one or more additional modules may also need to be initialized and configured with the CTMU module:

- Edge Source Generation: In addition to the external edge input pins, CCP1/CCP2 Special Event Triggers can be used as edge sources for the CTMU.
- Capacitance or Time Measurement: The CTMU module uses the A/D Converter to measure the voltage across a capacitor that is connected to one of the analog input channels.
- Pulse Generation: When generating system clock independent, output pulses, the CTMU module uses Comparator 2 and the associated comparator voltage reference.

## 26.4 Calibrating the CTMU Module

The CTMU requires calibration for precise measurements of capacitance and time, as well as for accurate time delay. If the application only requires measurement of a relative change in capacitance or time, calibration is usually not necessary. An example of a less precise application is a capacitive touch switch, in which the touch circuit has a baseline capacitance and the added capacitance of the human body changes the overall capacitance of a circuit.

If actual capacitance or time measurement is required, two hardware calibrations must take place:

- The current source needs calibration to set it to a precise current.
- The circuit being measured needs calibration to measure or nullify any capacitance other than that to be measured.

#### 26.4.1 CURRENT SOURCE CALIBRATION

The current source on board the CTMU module has a range of  $\pm 62\%$  nominal for each of three current ranges. For precise measurements, it is possible to measure and adjust this current source by placing a high-precision resistor, RCAL, onto an unused analog channel. An example circuit is shown in Figure 26-2.

To measure the current source:

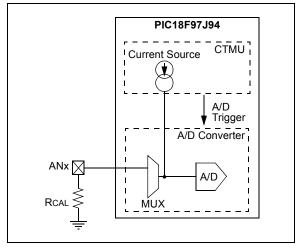

- 1. Initialize the A/D Converter.
- 2. Initialize the CTMU.
- Enable the current source by setting EDG1STAT (CTMUCON3<0>).
- Issue time delay for voltage across RCAL to stabilize and the A/D Sample-and-Hold (S/H) capacitor to charge.
- 5. Perform the A/D conversion.
- 6. Calculate the current source current using I = V/RCAL, where RCAL is a high-precision resistance and V is measured by performing an A/D conversion.

The CTMU current source may be trimmed with the ITRIMx bits in CTMUCON1, using an iterative process to get the exact current desired. Alternatively, the nominal value without adjustment may be used. That value may be stored by software for use in all subsequent capacitive or time measurements.

To calculate the optimal value for RCAL, the nominal current must be chosen.

For example, if the A/D Converter reference voltage is 3.3V, use 70% of full scale (or 2.31V) as the desired approximate voltage to be read by the A/D Converter. If the range of the CTMU current source is selected to be 0.55  $\mu$ A, the resistor value needed is calculated as RCAL = 2.31V/0.55  $\mu$ A, for a value of 4.2 MΩ. Similarly, if the current source is chosen to be 5.5  $\mu$ A, RCAL would be 420,000Ω, and 42,000Ω if the current source is set to 55  $\mu$ A.

#### FIGURE 26-2: CTMU CURRENT SOURCE CALIBRATION CIRCUIT

A value of 70% of full-scale voltage is chosen to make sure that the A/D Converter is in a range that is well above the noise floor. If an exact current is chosen to incorporate the trimming bits from CTMUCON1, the resistor value of RCAL may need to be adjusted accordingly. RCAL also may be adjusted to allow for available resistor values. RCAL should be of the highest precision available in light of the precision needed for the circuit that the CTMU will be measuring. A recommended minimum would be 0.1% tolerance.

The following examples show a typical method for performing a CTMU current calibration.

• Example 26-1 demonstrates how to initialize the A/D Converter and the CTMU.

This routine is typical for applications using both modules.

• Example 26-2 demonstrates one method for the actual calibration routine.

This method manually triggers the A/D Converter to demonstrate the entire step-wise process. It is also possible to automatically trigger the conversion by setting the CTMU's CTTRIG bit (CTMUCON<0>).

## EXAMPLE 26-1: SETUP FOR CTMU CALIBRATION ROUTINES

```
#include "pl8cxxx.h"
void setup(void)
{ //CTMUCON - CTMU Control register
  CTMUCON = 0 \times 00;
                         //make sure CTMU is disabled
  CTMUCON3 = 0x90;
  //CTMU continues to run when emulator is stopped,CTMU continues
  //to run in idle mode, Time Generation mode disabled, Edges are blocked
  //No edge sequence order, Analog current source not grounded, trigger
  //output disabled, Edge2 polarity = positive level, Edge2 source =
  //source 0, Edgel polarity = positive level, Edgel source = source 0,
  // Set Edge status bits to zero
   //CTMUCON1 - CTMU Current Control Register
  CTMUCON1 = 0 \times 01;
                         //0.55uA, Nominal - No Adjustment
//Setup AD converter;
TRISBbits.TRISB0=0;
  TRISAbits.TRISA2=1;
                                  //set channel 2 as an input
  ANCON1bits.ANSEL2=1;
                                  // Configured AN2 as an analog channel
  ADCON1Hbits.FORM=0b00;
                                 // Result format 1= Right justified
  ADCON1Lbits.SSRC=0b0111;
                                 // Acquisition time 7 = 20TAD 2 = 4TAD 1=2TAD
  ADCON3Hbits.SAMC=0b00111;
  ADCON3Lbits.ADCS=0x3F;
                                  // Clock conversion bits 6= FOSC/64 2=FOSC/32
                                  // ADCON1
                                  // Vref+ = AVdd
  ADCON2Hbits.PVCFG=0b00;
  ADCON2Hbits.NVCFG0=0;
                                  // Vref- = AVss
  ADCHS0Lbits.CHONA=0b000;
                                  // Select ADC channel
  ADCHS0Lbits.CHOSA=0b00010;
  ADCON1Hbits.ADON=1; // Turn on ADC
}
```

#### EXAMPLE 26-2: CTMU CURRENT CALIBRATION ROUTINE

```
#include "p18cxxx.h"

                                         //Get the value from the A/D
       PIR1bits.ADIF = 0;
                                         //Clear A/D Interrupt Flag
       VTot += Vread;
                                         //Add the reading to the total
   }
   Vavg = (float)(VTot/10.000);
                                         //Average of 10 readings
   Vcal = (float)(Vavg/ADSCALE*ADREF);
   CTMUISrc = Vcal/RCAL;
                                         //CTMUISrc is in 1/100ths of uA
```

## 26.4.2 CAPACITANCE CALIBRATION

There is a small amount of capacitance from the internal A/D Converter sample capacitor, as well as stray capacitance from the circuit board traces and pads that affect the precision of capacitance measurements. A measurement of the stray capacitance can be taken by making sure the desired capacitance to be measured has been removed.

After removing the capacitance to be measured:

- 1. Initialize the A/D Converter and the CTMU.
- 2. Set EDG1STAT (= 1).
- 3. Wait for a fixed delay of time, *t*.
- 4. Clear EDG1STAT.
- 5. Perform an A/D conversion.
- 6. Calculate the stray and A/D sample capacitances:

$$COFFSET = CSTRAY + CAD = (I \bullet t)/V$$

Where:

- I is known from the current source measurement step
- · t is a fixed delay
- V is measured by performing an A/D conversion

This measured value is then stored and used for calculations of time measurement or subtracted for capacitance measurement. For calibration, it is expected that the capacitance of CSTRAY + CAD is approximately known; CAD is approximately 4 pF.

An iterative process may be required to adjust the time, t, that the circuit is charged to obtain a reasonable voltage reading from the A/D Converter. The value of t may be determined by setting COFFSET to a theoretical value and solving for t. For example, if CSTRAY is theoretically calculated to be 11 pF, and V is expected to be 70% of VDD or 2.31V, t would be:

or 63 µs.

See Example 26-3 for a typical routine for CTMU capacitance calibration.

#### EXAMPLE 26-3: CTMU CAPACITANCE CALIBRATION ROUTINE

```
#include "pl8cxxx.h"
#define COUNT 25
                                          //@ 8MHz INTFRC = 62.5 us.
#define ETIME COUNT*2.5
                                          //time in uS
#define DELAY for(i=0;i<COUNT;i++)</pre>
#define ADSCALE 1023
                                         //for unsigned conversion 10 sig bits
#define ADREF 3.3
                                          //Vdd connected to A/D Vr+
#define RCAL .027
                                          //R value is 4200000 (4.2M)
                                          //scaled so that result is in
                                          //1/100th of uA
int main(void)
{
    int i;
   int j = 0;
                                          //index for loop
    unsigned int Vread = 0;
    float CTMUISrc, CTMUCap, Vavg, VTot, Vcal;
//assume CTMU and A/D have been setup correctly
//see Example 25-1 for CTMU & A/D setup
setup();
CTMUCONbits.CTMUEN = 1;
                                         //Enable the CTMU
    for(j=0;j<10;j++)</pre>
    {
        CTMUCONbits.IDISSEN = 1;
                                          //drain charge on the circuit
        DELAY;
                                          //wait 125us
        CTMUCONbits.IDISSEN = 0;
                                          //end drain of circuit
        CTMUCON3bits.EDG1STAT = 1;
                                          //Begin charging the circuit
                                          //using CTMU current source
        DELAY;
                                          //wait for 125us
        CTMUCON3bits.EDG1STAT = 0;
                                          //Stop charging circuit
        PIR1bits.ADIF = 0;
                                         //make sure A/D Int not set
        ADCON1Lbits.SAMP=1;
                                         //and begin A/D conv.
        while(!PIR1bits.ADIF);
                                          //Wait for A/D convert complete
        Vread = ADRES;
                                          //Get the value from the A/D
        PIR1bits.ADIF = 0;
                                          //Clear A/D Interrupt Flag
        VTot += Vread;
                                          /\,/\text{Add} the reading to the total
    }
    Vavg = (float)(VTot/10.000);
                                          //Average of 10 readings
    Vcal = (float)(Vavg/ADSCALE*ADREF);
                                          //CTMUISrc is in 1/100ths of uA
    CTMUISrc = Vcal/RCAL;
    CTMUCap = (CTMUISrc*ETIME/Vcal)/100;
}
```

#### 26.5 Measuring Capacitance with the CTMU

There are two ways to measure capacitance with the CTMU. The absolute method measures the actual capacitance value. The relative method only measures for any change in the capacitance.

#### 26.5.1 ABSOLUTE CAPACITANCE MEASUREMENT

For absolute capacitance measurements, both the current and capacitance calibration steps found in **Section 26.4 "Calibrating the CTMU Module**" should be followed.

To perform these measurements:

- 1. Initialize the A/D Converter.
- 2. Initialize the CTMU.
- 3. Set EDG1STAT.
- 4. Wait for a fixed delay, T.
- 5. Clear EDG1STAT.
- 6. Perform an A/D conversion.
- 7. Calculate the total capacitance, CTOTAL = (I \* T)/V, where:
  - I is known from the current source measurement step (Section 26.4.1 "Current Source Calibration")
  - · T is a fixed delay
  - V is measured by performing an A/D conversion
- Subtract the stray and A/D capacitance (COFFSET from Section 26.4.2 "Capacitance Calibration") from CTOTAL to determine the measured capacitance.

#### 26.5.2 CAPACITIVE TOUCH SENSE USING RELATIVE CHARGE MEASUREMENT

Not all applications require precise capacitance measurements. When detecting a valid press of a capacitance-based switch, only a relative change of capacitance needs to be detected.

In such an application when the switch is open (or not touched), the total capacitance is the capacitance of the combination of the board traces, the A/D Converter and other elements. A larger voltage will be measured by the A/D Converter. When the switch is closed (or touched), the total capacitance is larger due to the addition of the capacitance of the human body to the above listed capacitances and a smaller voltage will be measured by the A/D Converter.

To detect capacitance changes simply:

- 1. Initialize the A/D Converter and the CTMU.
- 2. Set EDG1STAT.
- 3. Wait for a fixed delay.
- 4. Clear EDG1STAT.
- 5. Perform an A/D conversion.

The voltage measured by performing the A/D conversion is an indication of the relative capacitance. In this case, no calibration of the current source or circuit capacitance measurement is needed. (For a sample software routine for a capacitive touch switch, see Example 26-4.)

#### EXAMPLE 26-4: CTMU ROUTINE FOR CAPACITIVE TOUCH SWITCH

```
#include "pl8cxxx.h"
#define COUNT 500
                                         //@ 8MHz = 125uS.
#define DELAY for(i=0;i<COUNT;i++)</pre>
#define OPENSW 1000
                                         //Un-pressed switch value
#define TRIP 300
                                         //Difference between pressed
                                         //and un-pressed switch
#define HYST 65
                                         //amount to change
                                         //from pressed to un-pressed
#define PRESSED 1
#define UNPRESSED 0
int main(void)
ł
   unsigned int Vread;
                                         //storage for reading
   unsigned int switchState;
   int i;
    //assume CTMU and A/D have been setup correctly
    //see Example 25-1 for CTMU & A/D setup
   setup();
   CTMUCONbits.CTMUEN = 1;
                                         //Enable the CTMU
   CTMUCONbits.IDISSEN = 1;
                                         //drain charge on the circuit
                                         //wait 125us
   DELAY;
   CTMUCONbits.IDISSEN = 0;
                                         //end drain of circuit
   CTMUCON3bits.EDG1STAT = 1;
                                         //Begin charging the circuit
                                         //using CTMU current source
                                         //wait for 125us
   DELAY;
   CTMUCON3bits.EDG1STAT = 0;
                                         //Stop charging circuit
   PIR1bits.ADIF = 0;
                                         //make sure A/D Int not set
   ADCON1Lbits.SAMP=1;;
                                         //and begin A/D conv.
   while(!PIR1bits.ADIF);
                                         //Wait for A/D convert complete
   Vread = ADRES;
                                         //Get the value from the A/D
    if(Vread < OPENSW - TRIP)
    {
       switchState = PRESSED;
   else if(Vread > OPENSW - TRIP + HYST)
    {
       switchState = UNPRESSED;
    }
```

## 26.6 Measuring Time with the CTMU Module

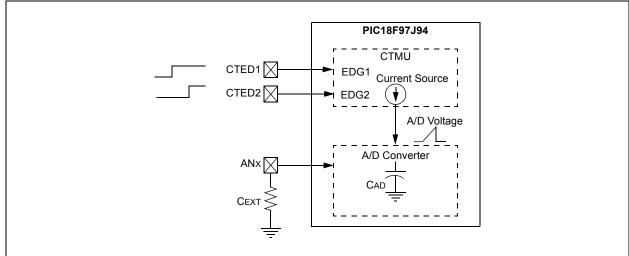

Time can be precisely measured after the ratio (C/I) is measured from the current and capacitance calibration step. To do that:

- 1. Initialize the A/D Converter and the CTMU.
- 2. Set EDG1STAT.
- 3. Set EDG2STAT.
- 4. Perform an A/D conversion.
- 5. Calculate the time between edges as T = (C/I) \* V, where:
  - I is calculated in the current calibration step (Section 26.4.1 "Current Source Calibration")
  - C is calculated in the capacitance calibration step (Section 26.4.2 "Capacitance Calibration")
  - V is measured by performing the A/D conversion

It is assumed that the time measured is small enough that the capacitance, CAD + CEXT, provides a valid voltage to the A/D Converter. For the smallest time measurement, always set the A/D Channel Select bits via ADCON1L/H to an unused A/D channel; the corresponding pin for which is not connected to any circuit board trace. This minimizes added stray capacitance, keeping the total circuit capacitance close to that of the A/D Converter itself (25 pF).

To measure longer time intervals, an external capacitor may be connected to an A/D channel and that channel selected whenever making a time measurement.

## FIGURE 26-3: CTMU TYPICAL CONNECTIONS AND INTERNAL CONFIGURATION FOR TIME MEASUREMENT

# 26.7 Measuring Temperature with the CTMU

The constant-current source provided by the CTMU module can be used for low-cost temperature measurement by exploiting a basic property of common and inexpensive diodes. An on-chip temperature sense diode is provided on A/D Channel 29 to further simplify design and cost.

#### 26.7.1 BASIC PRINCIPAL

We can show that the forward voltage (VF) of a P-N junction, such as a diode, is an extension of the equation for the junction's thermal voltage:

$$V_{\rm F} = \frac{kT}{q} \ln\left(1 - \frac{\rm IF}{\rm Is}\right)$$

where k is the Boltzmann constant  $(1.38 \times 10^{-23} \text{ J K}^{-1})$ , T is the absolute junction temperature in kelvin, q is the electron charge  $(1.6 \times 10^{-19} \text{ C})$ , IF is the forward current applied to the diode and Is is the diode's characteristic saturation current, which varies between devices.

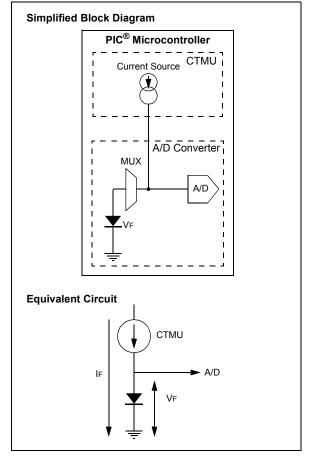

Since k and q are physical constants, and Is is a constant for the device, this only leaves T and IF as independent variables. If IF is held constant, it follows from the equation that VF will vary as a function of T. As the natural log term of the equation will always be negative, the temperature will be negatively proportional to VF. In other words, as temperature increases, VF decreases.

By using the CTMU's current source to provide a constant IF, it becomes possible to calculate the temperature by measuring the VF across the diode.

#### 26.7.2 IMPLEMENTATION

To implement this theory, all that is needed is to connect a regular junction diode to one of the microcontroller's A/D pins (Figure 26-2). The A/D channel multiplexer is shared by the CTMU and the A/D. To perform a measurement, the multiplexer is configured to select the pin connected to the diode. The CTMU current source is then turned on and an A/D conversion is performed on the channel. As shown in the equivalent circuit diagram in Figure 26-4, the diode is driven by the CTMU at IF. The resulting VF across the diode is measured by the A/D. A code snippet is shown in Example 26-5.

#### FIGURE 26-4: CTMU TEMPERATURE MEASUREMENT CIRCUIT

#### EXAMPLE 26-5: CTMU ROUTINE FOR TEMPERATURE MEASUREMENT USING INTERNAL DIODE

<pre>// Initialize CTMU CTMUICON = 0x03; CTMUCONbits.CTMUEN = 1; CTMUCON3bits.EDG1STAT = 1;</pre>	
ADCON1Hbits.FORM = 0; ADCON1Hbits.MODE12 = 0; ADCHS0Lbits.CHOSA = 0x18;	// Right Justified // 12-Bit A/D Operation // Enable ADC and connect to Internal diode
ADCON1Hbits.ADON = 1;	// Enable ADC
Note: The temperature diode is not cal	librated or standardized; the user must calibrate the diode to their application.

## 26.8 Operation During Sleep/Idle Modes

#### 26.8.1 SLEEP MODE

When the device enters any Sleep mode, the CTMU module current source is always disabled. If the CTMU is performing an operation that depends on the current source when Sleep mode is invoked, the operation may not terminate correctly. Capacitance and time measurements may return erroneous values.

## 26.8.2 IDLE MODE

The behavior of the CTMU in Idle mode is determined by the CTMUSIDL bit (CTMUCON<5>). If CTMUSIDL is cleared, the module will continue to operate in Idle mode. If CTMUSIDL is set, the module's current source is disabled when the device enters Idle mode. In this case, if the module is performing an operation when Idle mode is invoked, the results will be similar to those with Sleep mode.

## 26.9 Effects of a Reset on CTMU

Upon Reset, all registers of the CTMU are cleared. This disables the CTMU module, turns off its current source and returns all configuration options to their default settings. The module needs to be re-initialized following any Reset.

If the CTMU is in the process of taking a measurement at the time of Reset, the measurement will be lost. A partial charge may exist on the circuit that was being measured, which should be properly discharged before the CTMU makes subsequent attempts to take a measurement. The circuit is discharged by setting and clearing the IDISSEN bit (CTMUCON<1>) while the A/D Converter is connected to the appropriate channel.

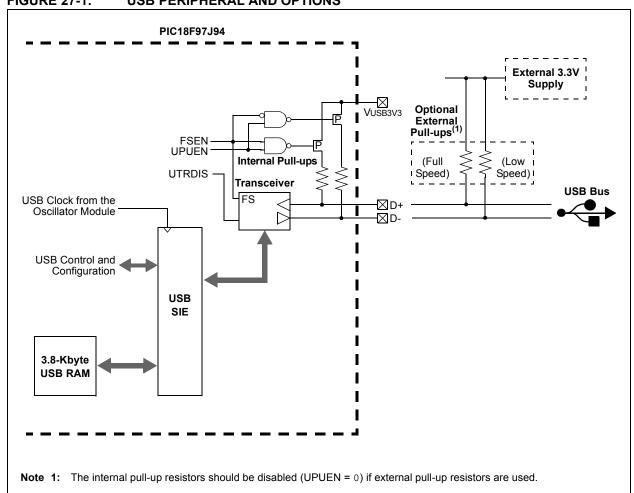

## 27.0 UNIVERSAL SERIAL BUS (USB)

This section describes the details of the USB peripheral. Because of the very specific nature of the module, some knowledge of USB is expected. Some high-level USB information is provided in Section 27.9 "Overview of USB" only for application design reference. Designers are encouraged to refer to the official specification published by the USB Implementers Forum (USB-IF) for the latest information. USB Specification Revision 2.0 is the most current specification at the time of publication of this document.

## 27.1 Overview of the USB Peripheral

PIC18FXXJ94 devices contain a full-speed and lowspeed, compatible USB Serial Interface Engine (SIE) that allows fast communication between any USB host and the PIC<sup>®</sup> MCU. The SIE can be interfaced directly to the USB, utilizing the internal transceiver.

Some special hardware features have been included to improve performance. Dual access port memory in the device's data memory space (USB RAM) has been supplied to share Direct Memory Access (DMA) between the microcontroller core and the SIE. Buffer descriptors are also provided, allowing users to freely program endpoint memory usage within the USB RAM space. Figure 27-1 provides a general overview of the USB peripheral and its features.

## 27.2 USB Status and Control

The operation of the USB module is configured and managed through three control registers. In addition, a total of 22 registers are used to manage the actual USB transactions. The registers are:

- USB Control Register (UCON)
- USB Configuration Register (UCFG)
- USB Transfer STATUS Register (USTAT)
- USB Device Address Register (UADDR)
- Frame Number Registers (UFRMH:UFRML)
- Endpoint Enable Registers 0 through 15 (UEPn)

#### 27.2.1 USB CONTROL REGISTER (UCON)

The USB Control register (Register 27-1) contains bits needed to control the module behavior during transfers. The register contains bits that control the following:

- Main USB Peripheral Enable
- Ping-Pong Buffer Pointer Reset
- Control of the Suspend mode
- Packet Transfer Disable

In addition, the USB Control register contains a Status bit, SE0 (UCON<5>), which is used to indicate the occurrence of a single-ended zero on the bus. When the USB module is enabled, this bit should be monitored to determine whether the differential data lines have come out of a single-ended zero condition. This helps to differentiate the initial power-up state from the USB Reset signal.

The overall operation of the USB module is controlled by the USBEN bit (UCON<3>). Setting this bit activates the module and resets all of the PPBI bits in the Buffer Descriptor Table (BDT) to '0'. This bit also activates the internal pull-up resistors if they are enabled. Thus, this bit can be used as a soft attach/detach to the USB. Although all status and control bits are ignored when this bit is clear, the module needs to be fully preconfigured prior to setting this bit. The USB clock source should have been already configured for the correct frequency and running. If the PLL is being used, it should be enabled for at least 2 ms (enough time for the PLL to lock) before attempting to set the USBEN bit.

Note: When disabling the USB module, make sure the SUSPND bit (UCON<1>) is clear prior to clearing the USBEN bit. Clearing the USBEN bit when the module is in the suspended state may prevent the module from fully powering down

#### REGISTER 27-1: UCON: USB CONTROL REGISTER

U-0	R/W-0	R-x	R/C-0	R/W-0	R/W-0	R/W-0	U-0
—	PPBRST <sup>(2)</sup>	SE0	PKTDIS	USBEN <sup>(1)</sup>	RESUME	SUSPND	—
bit 7							bit 0

Legend:	C = Clearable bit

-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

bit 7	Unimplemented: Read as '0'
bit 6	PPBRST: Ping-Pong Buffers Reset bit <sup>(2)</sup>
	<ul> <li>1 = Reset all Ping-Pong Buffer Pointers to the Even Buffer Descriptor (BD) banks</li> <li>0 = Ping-Pong Buffer Pointers are not being reset</li> </ul>
bit 5	SE0: Live Single-Ended Zero Flag bit
	<ul><li>1 = Single-ended zero is active on the USB bus</li><li>0 = No single-ended zero is detected</li></ul>
bit 4	PKTDIS: Packet Transfer Disable bit
	<ul> <li>1 = SIE token and packet processing are disabled, automatically set when a SETUP token is received</li> <li>0 = SIE token and packet processing are enabled</li> </ul>
bit 3	USBEN: USB Module Enable bit <sup>(1)</sup>
	<ul> <li>1 = USB module and supporting circuitry are enabled (device attached)</li> <li>0 = USB module and supporting circuitry are disabled (device detached)</li> </ul>
bit 2	RESUME: Resume Signaling Enable bit
	<ul><li>1 = Resume signaling is activated</li><li>0 = Resume signaling is disabled</li></ul>
bit 1	SUSPND: Suspend USB bit
	<ul> <li>1 = USB module and supporting circuitry are in Power Conserve mode, SIE clock is inactive</li> <li>0 = USB module and supporting circuitry are in normal operation, SIE is clocked at the configured rate</li> </ul>
bit 0	Unimplemented: Read as '0'

- Note 1: Make sure the USB clock source is correctly configured before setting this bit.
  - 2: There should be at least four cycles of delay between the setting and PPBRST.

The PPBRST bit (UCON<6>) controls the Reset status when Double-Buffering mode (ping-pong buffering) is used. When the PPBRST bit is set, all Ping-Pong Buffer Pointers are set to the Even buffers. PPBRST has to be cleared by firmware. This bit is ignored in buffering modes not using ping-pong buffering.

The PKTDIS bit (UCON<4>) is a flag indicating that the SIE has disabled packet transmission and reception. This bit is set by the SIE when a SETUP token is received to allow setup processing. This bit cannot be set by the microcontroller, only cleared; clearing it allows the SIE to continue transmission and/or reception. Any pending events within the Buffer Descriptor Table (BDT) will still be available, indicated within the USTAT register's FIFO buffer.

The RESUME bit (UCON<2>) allows the peripheral to perform a remote wake-up by executing resume signaling. To generate a valid remote wake-up, firmware must set RESUME for 10 ms and then clear the bit. For more information on resume signaling, see Sections 7.1.7.5, 11.4.4 and 11.9 in the "USB 2.0 Specification".

The SUSPND bit (UCON<1>) places the module and supporting circuitry in a Low-Power mode. The input clock to the SIE is also disabled. This bit should be set by the software in response to an IDLEIF interrupt. It should be reset by the microcontroller firmware after an ACTVIF interrupt is observed. When this bit is active, the device remains attached to the bus but the transceiver outputs remain Idle. The voltage on the VUSB3V3 pin may vary depending on the value of this bit. Setting this bit before a IDLEIF request will result in unpredictable bus behavior.

**Note:** While in Suspend mode, a typical buspowered USB device is limited to 2.5 mA of current. This is the complete current which may be drawn by the PIC MCU device and its supporting circuitry. Care should be taken to assure minimum current draw when the device enters Suspend mode.

# 27.2.2 USB CONFIGURATION REGISTER (UCFG)

Prior to communicating over USB, the module's associated internal and/or external hardware must be configured. Most of the configuration is performed with the UCFG register (Register 27-2). The UFCG register contains most of the bits that control the system-level behavior of the USB module. These include:

- Bus Speed (full speed versus low speed)
- On-Chip Pull-up Resistor Enable
- On-Chip Transceiver Enable
- Ping-Pong Buffer Usage

The UCFG register also contains two bits, which aid in module testing, debugging and USB certifications. These bits control output enable state monitoring and eye pattern generation.

Note:	The USB speed, transceiver and pull-up should only be configured during the module setup phase. It is not recom-
	mended to switch these settings while the module is enabled.

#### 27.2.2.1 Internal Transceiver

The USB peripheral has a built-in, "USB 2.0 Specification", full-speed and low-speed capable transceiver, internally connected to the SIE. This feature is useful for low-cost, single chip applications. The UTRDIS bit (UCFG<3>) controls the transceiver; it is enabled by default (UTRDIS = 0). The FSEN bit (UCFG<2>) controls the transceiver speed; setting this bit enables full-speed operation.

The on-chip USB pull-up resistors are controlled by the UPUEN bit (UCFG<4>). They can only be selected when the on-chip transceiver is enabled.

The internal USB transceiver obtains power from the VUSB3V3 pin. In order to meet USB signalling level specifications, VUSB3V3 must be supplied with a voltage source between 3.0V and 3.6V. The best electrical signal quality is obtained when a 3.3V supply is used and locally bypassed with a high quality ceramic capacitor (ex: 0.1  $\mu$ F). The capacitor should be placed as close as possible to the VUSB3V3 and VSS pins.

VUSB3V3 should always be maintained  $\geq$  VDD. If the USB module is not used, but RC4 or RC5 are used as general purpose inputs, VUSB3V3 should still be connected to a power source (such as VDD). The input thresholds for the RC4 and RC5 pins are dependent upon the VUSB3V3 supply level.

The D+ and D- signal lines can be routed directly to their respective pins on the USB connector or cable (for hard-wired applications). No additional resistors, capacitors or magnetic components are required, as the D+ and D- drivers have controlled slew rate and output impedance, intended to match with the characteristic impedance of the USB cable.

In order to achieve optimum USB signal quality, the D+ and D- traces between the microcontroller and USB connector (or cable) should be less than 19 cm long. Both traces should be equal in length and they should be routed parallel to each other. Ideally, these traces should be designed to have a characteristic impedance matching that of the USB cable.

#### 27.2.2.2 Internal Pull-up Resistors

The PIC18FXXJ94 devices have built-in pull-up resistors, designed to meet the requirements for low-speed and full-speed USB. The UPUEN bit (UCFG<4>) enables the internal pull-ups. Figure 27-1 shows the pull-ups and their control.

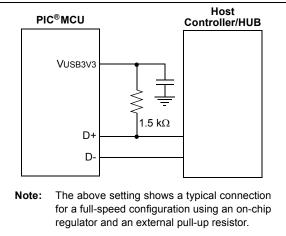

Note: A compliant USB device should never source any current onto the +5V VBUS line of the USB cable. Additionally, USB devices should not source any current on the D+ and D- data lines whenever the +5V VBUS line is less than 1.17V. In order to be USB compliant, applications which are not purely bus-powered should monitor the VBUS line, and avoid turning on the USB module and the D+ or D- pull-up resistor until VBUS is greater than 1.17V. VBUS can be connected to and monitored by a 5V tolerant I/O pin, or if a resistive divider is used, by an analog capable pin.

#### 27.2.2.3 External Pull-up Resistors

External pull-ups may also be used. The VUSB3V3 pin may be used to pull up D+ or D-. The pull-up resistor must be 1.5 k $\Omega$  (±5%) as required by the USB specifications.

Figure 27-2 provides an example of external circuitry.

#### FIGURE 27-2: EXTERNAL CIRCUITRY

## 27.2.2.4 Ping-Pong Buffer Configuration

The usage of ping-pong buffers is configured using the PPB<1:0> bits. Refer to **Section 27.4.4** "**Ping-Pong Buffering**" for a complete explanation of the ping-pong buffers.

#### 27.2.2.5 Eye Pattern Test Enable

An automatic eye pattern test can be generated by the module when the UCFG<7> bit is set. The eye pattern output will be observable based on module settings, meaning that the user is first responsible for configuring the SIE clock settings, pull-up resistor and Transceiver mode. In addition, the module has to be enabled.

Once UTEYE is set, the module emulates a switch from a receive to transmit state and will start transmitting a J-K-J-K bit sequence (K-J-K-J for full speed). The sequence will be repeated indefinitely while the Eye Pattern Test mode is enabled.

Note that this bit should never be set while the module is connected to an actual USB system. This Test mode is intended for board verification to aid with USB certification tests. It is intended to show a system developer the noise integrity of the USB signals which can be affected by board traces, impedance mismatches and proximity to other system components. It does not properly test the transition from a receive to a transmit state. Although the eye pattern is not meant to replace the more complex USB certification test, it should aid during first order system debugging.

#### 27.2.3 USB STATUS REGISTER (USTAT)

The USB STATUS register reports the transaction status within the SIE. When the SIE issues a USB transfer complete interrupt, USTAT should be read to determine the status of the transfer. USTAT contains the transfer endpoint number, direction and Ping-Pong Buffer Pointer value (if used).

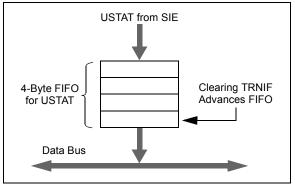

Note:	The data in the USB STATUS register is
	valid only when the TRNIF interrupt flag is
	asserted.

The USTAT register is actually a read window into a 4-byte status FIFO, maintained by the SIE. It allows the microcontroller to process one transfer while the SIE processes additional endpoints (Figure 27-3). When the SIE completes using a buffer for reading or writing data, it updates the USTAT register. If another USB transfer is performed before a transaction complete interrupt is serviced, the SIE will store the status of the next transfer into the status FIFO.

Clearing the Transfer Complete Flag bit, TRNIF, causes the SIE to advance the FIFO. If the next data in the FIFO holding register is valid, the SIE will reassert the interrupt within 5 TCY of clearing TRNIF. If no additional data is present, TRNIF will remain clear; USTAT data will no longer be reliable.

**Note:** If an endpoint request is received while the USTAT FIFO is full, the SIE will automatically issue a NAK back to the host.

#### FIGURE 27-3: USTAT FIFO

Note 1: This bit is only valid for endpoints with available Even and Odd BD registers.

#### 27.2.4 USB ENDPOINT CONTROL

Each of the 16 possible bidirectional endpoints has its own independent control register, UEPn (where 'n' represents the endpoint number). Each register has an identical complement of control bits.

Register 27-4 provides the prototype.

The EPHSHK bit (UEPn<4>) controls handshaking for the endpoint; setting this bit enables USB handshaking. Typically, this bit is always set except when using isochronous endpoints.

The EPCONDIS bit (UEPn<3>) is used to enable or disable USB control operations (SETUP) through the endpoint. Clearing this bit enables SETUP transactions. Note that the corresponding EPINEN and EPOUTEN bits must be set to enable IN and OUT transactions. For Endpoint 0, this bit should always be cleared since the USB specifications identify Endpoint 0 as the default control endpoint.

The EPOUTEN bit (UEPn<2>) is used to enable or disable USB OUT transactions from the host. Setting this bit enables OUT transactions. Similarly, the EPINEN bit (UEPn<1>) enables or disables USB IN transactions from the host.

The EPSTALL bit (UEPn<0>) is used to indicate a STALL condition for the endpoint. If a STALL is issued on a particular endpoint, the EPSTALL bit for that endpoint pair will be set by the SIE. This bit remains set until it is cleared through firmware or until the SIE is reset.

	1 = Endpoint n has issued one or more STALL packets
	0 = Endpoint n has not issued any STALL packets

#### 27.2.5 USB ADDRESS REGISTER (UADDR)

The USB Address register contains the unique USB address that the peripheral will decode when active. UADDR is reset to 00h when a USB Reset is received, indicated by URSTIF, or when a Reset is received from the microcontroller. The USB address must be written by the microcontroller during the USB setup phase (enumeration) as part of the Microchip USB firmware support.

## 27.2.6 USB FRAME NUMBER REGISTERS (UFRMH:UFRML)

The Frame Number registers contain the 11-bit frame number. The low-order byte is contained in UFRML, while the three high-order bits are contained in UFRMH. The register pair is updated with the current frame number whenever a SOF token is received. For the microcontroller, these registers are read-only. The Frame Number registers are primarily used for isochronous transfers. The contents of the UFRMH and UFRML registers are only valid when the 48 MHz SIE clock is active (i.e., contents are inaccurate when SUSPND (UCON<1>) bit = 1).

## 27.3 USB RAM

USB data moves between the microcontroller core and the SIE through a memory space, known as the USB RAM. This is a special dual access memory that is mapped into the normal data memory space in Banks 0 through 14 (00h to EBFh), for a total of 3.8 Kbytes (Figure 27-4).

Bank 13 (D00h through DFFh) is used specifically for endpoint buffer control, while Banks 0 through 12 and Bank 14 are available for USB data. Depending on the type of buffering being used, all but 8 bytes of Bank 13 may also be available for use as USB buffer space.

Although USB RAM is available to the microcontroller as data memory, the sections that are being accessed by the SIE should not be accessed by the microcontroller. A semaphore mechanism is used to determine the access to a particular buffer at any given time. This is discussed in **Section 27.4.1.1 "Buffer Ownership**".

#### FIGURE 27-4:

	SFRs	FFFh

## 27.4 Buffer Descriptors and the Buffer Descriptor Table

The registers in Bank 13 are used specifically for endpoint buffer control in a structure known as the Buffer Descriptor Table (BDT). This provides a flexible method for users to construct and control endpoint buffers of various lengths and configuration.

The BDT is composed of Buffer Descriptors (BD) which are used to define and control the actual buffers in the USB RAM space. Each BD, in turn, consists of four registers, where n represents one of the 64 possible BDs (range of 0 to 63):

- BDnSTAT: BD STATUS Register
- BDnCNT: BD Byte Count Register
- · BDnADRL: BD Address Low Register
- BDnADRH: BD Address High Register

BDs always occur as a four-byte block in the sequence, BDnSTAT:BDnCNT:BDnADRL:BDnADRH. The address of BDnSTAT is always an offset of (4n - 1, in hexadecimal) from D00h, with n being the buffer descriptor number.

Depending on the buffering configuration used (Section 27.4.4 "Ping-Pong Buffering"), there are up to 32, 33 or 64 sets of buffer descriptors. At a minimum, the BDT must be at least 8 bytes long. This is because the USB Specification mandates that every device must have Endpoint 0 with both input and output for initial setup. Depending on the endpoint and buffering configuration, the BDT can be as long as 256 bytes.

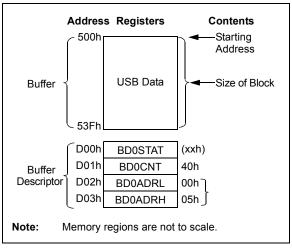

Although they can be thought of as Special Function Registers, the Buffer Descriptor Status and Address registers are not hardware mapped, as conventional microcontroller SFRs in Bank 15 are. If the endpoint corresponding to a particular BD is not enabled, its registers are not used. Instead of appearing as unimplemented addresses, however, they appear as available RAM. Only when an endpoint is enabled by setting the UEPn<1> bit does the memory at those addresses become functional as BD registers. As with any address in the data memory space, the BD registers have an indeterminate value on any device Reset.

Figure 27-5 provides an example of a BD for a 64-byte buffer, starting at 500h. A particular set of BD registers is only valid if the corresponding endpoint has been enabled using the UEPn register. All BD registers are available in USB RAM. The BD for each endpoint should be set up prior to enabling the endpoint.

#### 27.4.1 BD STATUS AND CONFIGURATION

Buffer descriptors not only define the size of an endpoint buffer, but also determine its configuration and control. Most of the configuration is done with the BD STATUS register, BDnSTAT. Each BD has its own unique and correspondingly numbered BDnSTAT register.

#### FIGURE 27-5: EXAMPLE OF A BUFFER DESCRIPTOR

Unlike other control registers, the bit configuration for the BDnSTAT register is context-sensitive. There are two distinct configurations, depending on whether the microcontroller or the USB module is modifying the BD and buffer at a particular time. Only three bit definitions are shared between the two.

#### 27.4.1.1 Buffer Ownership

Because the buffers and their BDs are shared between the CPU and the USB module, a simple semaphore mechanism is used to distinguish which is allowed to update the BD and associated buffers in memory.

This is done by using the UOWN bit (BDnSTAT<7>) as a semaphore to distinguish which is allowed to update the BD and associated buffers in memory. UOWN is the only bit that is shared between the two configurations of BDnSTAT.

When UOWN is clear, the BD entry is "owned" by the microcontroller core. When the UOWN bit is set, the BD entry and the buffer memory are "owned" by the USB peripheral. The core should not modify the BD or its corresponding data buffer during this time. Note that the microcontroller core can still read BDnSTAT while the SIE owns the buffer and vice versa.

The buffer descriptors have a different meaning based on the source of the register update. Prior to placing ownership with the USB peripheral, the user can configure the basic operation of the peripheral through the BDnSTAT bits. During this time, the byte count and buffer location registers can also be set.

When UOWN is set, the user can no longer depend on the values that were written to the BDs. From this point, the SIE updates the BDs as necessary, overwriting the original BD values. The BDnSTAT register is updated by the SIE with the token PID and the transfer count, BDnCNT, is updated. The BDnSTAT byte of the BDT should always be the last byte updated when preparing to arm an endpoint. The SIE will clear the UOWN bit when a transaction has completed.

No hardware mechanism exists to block access when the UOWN bit is set. Thus, unexpected behavior can occur if the microcontroller attempts to modify memory when the SIE owns it. Similarly, reading such memory may produce inaccurate data until the USB peripheral returns ownership to the microcontroller.

#### 27.4.1.2 BDnSTAT Register (CPU Mode)

When UOWN = 0, the microcontroller core owns the BD. At this point, the other seven bits of the register take on control functions.

The Data Toggle Sync Enable bit, DTSEN (BDnSTAT<3>), controls data toggle parity checking. Setting DTSEN enables data toggle synchronization by the SIE. When enabled, it checks the data packet's parity against the value of DTS (BDnSTAT<6>). If a packet arrives with an incorrect synchronization, the data will essentially be ignored. It will not be written to the USB RAM and the USB transfer complete interrupt flag will not be set. The SIE will send an ACK token back to the host to Acknowledge receipt, however. The effects of the DTSEN bit on the SIE are summarized in Table 27-1.

The Buffer Stall bit, BSTALL (BDnSTAT<2>), provides support for control transfers, usually one-time stalls on Endpoint 0. It also provides support for the SET\_FEA-TURE/CLEAR\_FEATURE commands specified in Chapter 9 of the USB Specification; typically, continuous STALLs to any endpoint other than the default control endpoint.

The BSTALL bit enables buffer stalls. Setting BSTALL causes the SIE to return a STALL token to the host if a received token would use the BD in that location. The EPSTALL bit in the corresponding UEPn Control register is set and a STALL interrupt is generated when a STALL is issued to the host. The UOWN bit remains set and the BDs are not changed unless a SETUP token is received. In this case, the STALL condition is cleared and the ownership of the BD is returned to the microcontroller core.

The BC<9:8> bits (BDnSTAT<1:0>) store the two most significant digits of the SIE byte count. The lower 8 digits are stored in the corresponding BDnCNT register. See **Section 27.4.2 "BD Byte Count"** for more information.

OUT Packet	BDnSTAT Settings		Device Response after Receiving Packet				
from Host	DTSEN	DTS	Handshake	UOWN	TRNIF	BDnSTAT and USTAT Status

- **2:** This bit is ignored unless DTSEN = 1.
- 3: If these bits are set, USB communication may not work. Hence, these bits should always be maintained as '0'.

#### 27.4.1.3 BDnSTAT Register (SIE Mode)

When the BD and its buffer are owned by the SIE, most of the bits in BDnSTAT take on a different meaning. The configuration is shown in Register 27-6. Once UOWN is set, any data or control settings previously written there by the user will be overwritten with data from the SIE.

The BDnSTAT register is updated by the SIE with the token Packet Identifier (PID) which is stored in BDnSTAT<5:2>. The transfer count in the corresponding BDnCNT register is updated. Values that overflow the 8-bit register carry over to the two most significant digits of the count, stored in BDnSTAT<1:0>.

#### 27.4.2 BD BYTE COUNT

The byte count represents the total number of bytes that will be transmitted during an IN transfer. After an IN transfer, the SIE will return the number of bytes sent to the host.

For an OUT transfer, the byte count represents the maximum number of bytes that can be received and stored in USB RAM. After an OUT transfer, the SIE will return the actual number of bytes received. If the number of bytes received exceeds the corresponding byte count, the data packet will be rejected and a NAK handshake will be generated. When this happens, the byte count will not be updated.

The 10-bit byte count is distributed over two registers. The lower 8 bits of the count reside in the BDnCNT register; the upper two bits reside in BDnSTAT<1:0>. This represents a valid byte range of 0 to 1023.

#### 27.4.3 BD ADDRESS VALIDATION

The BD Address register pair contains the starting RAM address location for the corresponding endpoint buffer. No mechanism is available in hardware to validate the BD address.

If the value of the BD address does not point to an address in the USB RAM, or if it points to an address within another endpoint's buffer, data is likely to be lost or overwritten. Similarly, overlapping a receive buffer (OUT endpoint) with a BD location in use can yield unexpected results. When developing USB applications, the user may want to consider the inclusion of software-based address validation in their code.

## REGISTER 27-6: BDnSTAT: BUFFER DESCRIPTOR n STATUS REGISTER (BD0STAT THROUGH BD63STAT), SIE MODE (DATA RETURNED BY THE SIE TO THE MCU)

R/W-x	r-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x	R/W-x

#### bit 7 UOWN: USB Own bit

1 = The SIE owns the BD and its corresponding buffer

bit 6 **Reserved:** Not written by the SIE

bit 5-2 **PID<3:0>:** Packet Identifier bits

The received token PID value of the last transfer (IN, OUT or SETUP transactions only).

bit 1-0 BC<9:8>: Byte Count 9 and 8 bits These bits are updated by the SIE to reflect the actual number of bytes received on an OUT transfer and the actual number of bytes transmitted on an IN transfer.

## 27.4.4 PING-PONG BUFFERING

An endpoint is defined to have a ping-pong buffer when it has two sets of BD entries: one set for an Even transfer and one set for an Odd transfer. This allows the CPU to process one BD while the SIE is processing the other BD. Double-buffering BDs in this way allows for maximum throughput to/from the USB.

The USB module supports four modes of operation:

- No ping-pong support
- Ping-pong buffer support for OUT Endpoint 0 only
- · Ping-pong buffer support for all endpoints
- Ping-pong buffer support for all other endpoints except Endpoint 0

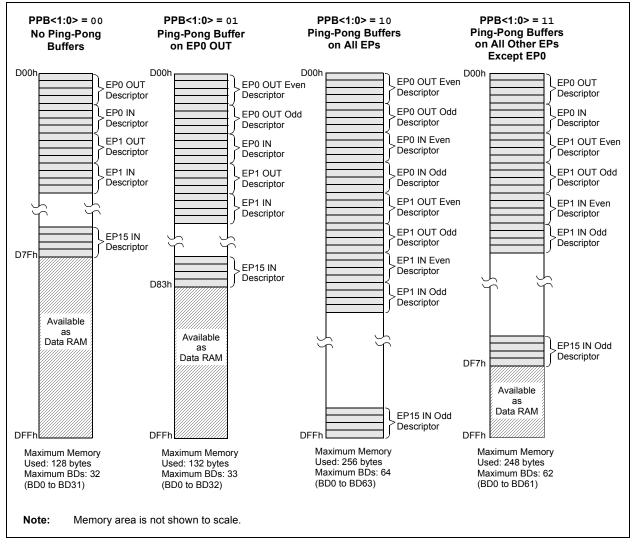

The ping-pong buffer settings are configured using the PPB<1:0> bits in the UCFG register.

The USB module keeps track of the Ping-Pong Pointer individually for each endpoint. All pointers are initially reset to the Even BD when the module is enabled. After the completion of a transaction (UOWN cleared by the SIE), the pointer is toggled to the Odd BD. After the completion of the next transaction, the pointer is toggled back to the Even BD and so on.

The Even/Odd status of the last transaction is stored in the PPBI bit of the USTAT register. The user can reset all Ping-Pong Pointers to Even using the PPBRST bit.

Figure 27-6 shows the four different modes of operation and how USB RAM is filled with the BDs.

BDs have a fixed relationship to a particular endpoint, depending on the buffering configuration. Table 27-2 provides the mapping of BDs to endpoints. This relationship also means that gaps may occur in the BDT if endpoints are not enabled contiguously. This, theoretically, means that the BDs for disabled endpoints could be used as buffer space. In practice, users should avoid using such spaces in the BDT unless a method of validating BD addresses is implemented.

# TABLE 27-2:ASSIGNMENT OF BUFFER DESCRIPTORS FOR THE DIFFERENT<br/>BUFFERING MODES

	BDs Assigned to Endpoint								
Endpoint	Mode 0 (No Ping-Pong) (Pir		Mode 1 (Ping-Pong on EP0 OUT)		Mod (Ping-Pong		Mode 3 (Ping-Pong on All Other EPs, except EP0)

TABLE 27-3:         SUMMARY OF USB BUFFER DESCRIPTOR TABLE REGISTERS
--

Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	
BDnSTAT <sup>(1)</sup>	UOWN	DTS <sup>(4)</sup>	PID3 <sup>(2)</sup>	PID2 <sup>(2)</sup>	PID1 <sup>(2)</sup> DTSEN <sup>(3)</sup>	PID0 <sup>(2)</sup> BSTALL <sup>(3)</sup>	BC9	BC8	
BDnCNT <sup>(1)</sup>		Byte Count							
BDnADRL <sup>(1)</sup>		Buffer Address Low							
BDnADRH <sup>(1)</sup>				Buffer Ad	dress High				

**Note 1:** For buffer descriptor registers, n may have a value of 0 to 63. For the sake of brevity, all 64 registers are shown as one generic prototype. All registers have indeterminate Reset values (xxxx xxxx).

2: Bits 5 through 2 of the BDnSTAT register are used by the SIE to return PID<3:0> values once the register is turned over to the SIE (UOWN bit is set). Once the registers have been under SIE control, the values written for DTSEN and BSTALL are no longer valid.

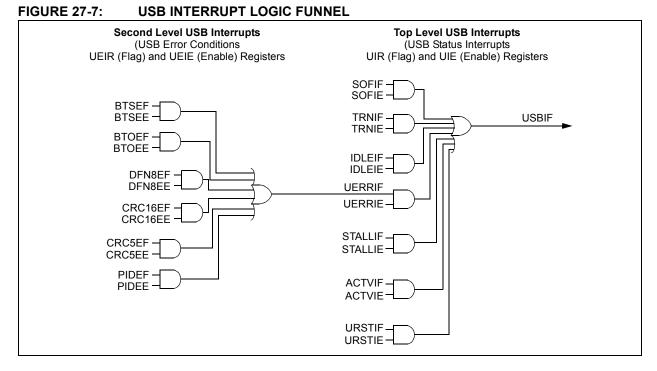

**3:** Prior to turning the buffer descriptor over to the SIE (UOWN bit is cleared), bits 5 through 2 of the BDnSTAT register are used to configure the DTSEN and BSTALL settings.

4: This bit is ignored unless DTSEN = 1.

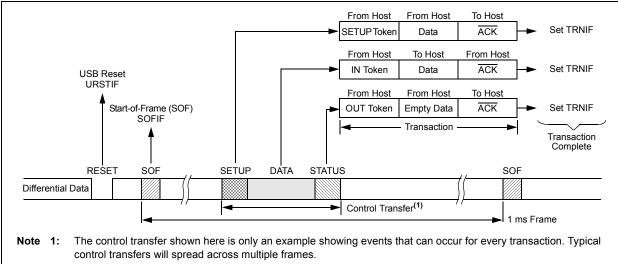

## 27.5 USB Interrupts

The USB module can generate multiple interrupt conditions. To accommodate all of these interrupt sources, the module is provided with its own interrupt logic structure, similar to that of the microcontroller. USB interrupts are enabled with one set of control registers and trapped with a separate set of flag registers. All sources are funneled into a single USB Oscillator Fail Interrupt Flag bit, USBIF (PIR2<4>), in the microcontroller's interrupt logic. Figure 27-7 provides the interrupt logic for the USB module. There are two layers of interrupt registers in the USB module. The top level consists of overall USB status interrupts; these are enabled and flagged in the UIE and UIR registers, respectively. The second level consists of USB error conditions, which are enabled and flagged in the UEIR and UEIE registers. An interrupt condition in any of these triggers a USB Error Interrupt Flag (UERRIF) in the top level.

Interrupts may be used to trap routine events in a USB transaction. Figure 27-8 provides some common events within a USB frame and its corresponding interrupts.

#### 27.5.1 USB INTERRUPT STATUS REGISTER (UIR)

The USB Interrupt STATUS register (Register 27-7) contains the flag bits for each of the USB status interrupt sources. Each of these sources has a corresponding interrupt enable bit in the UIE register. All of the USB status flags are ORed together to generate the USBIF interrupt flag for the microcontroller's interrupt funnel.

Once an interrupt bit has been set by the SIE, it must be cleared in software by writing a '0'. The flag bits can also be set in software, which can aid in firmware debugging. When the USB module is in the Low-Power Suspend mode (UCON<1> = 1), the SIE does not get clocked. When in this state, the SIE cannot process packets, and therefore, cannot detect new interrupt conditions other than the Activity Detect Interrupt, ACTVIF. The ACTVIF bit is typically used by USB firmware to detect when the microcontroller should bring the USB module out of the Low-Power Suspend mode (UCON<1> = 0).

Note 1: Or	ice an Idle state is detected, the use	er may want to place the USB module in Suspend mode.
<b>2:</b> Cle	earing this bit will cause the USTAT	FIFO to advance (valid only for IN, OUT and SETUP tokens).
<b>3:</b> Th	is bit is typically unmasked only follo	lowing the detection of a UIDLE interrupt event.
<b>4</b> : Or	ly error conditions enabled through	the UEIE register will set this bit. This bit is a Status bit only and

4: Only error conditions enabled through the UEIE register will set this bit. This bit is a Status bit only and cannot be set or cleared by the user.

## 27.5.1.1 Bus Activity Detect Interrupt Bit (ACTVIF)

The ACTVIF bit cannot be cleared immediately after the USB module wakes up from Suspend mode or while the USB module is suspended. A few clock cycles are required to synchronize the internal hardware state machine before the ACTVIF bit can be cleared by firmware. Clearing the ACTVIF bit before the internal hardware is synchronized may not have an effect on the value of ACTVIF. Additionally, if the USB module uses the clock from the 96 MHz PLL source, then after clearing the SUSPND bit, the USB module

#### may not be immediately operational while waiting for the 96 MHz PLL to lock. The application code should clear the ACTVIF flag as provided in Example 27-1.

Note: Only one ACTVIF interrupt is generated when resuming from the USB bus Idle condition. If user firmware clears the ACTVIF bit, the bit will not immediately become set again, even when there is continuous bus traffic. Bus traffic must cease long enough to generate another IDLEIF condition before another ACTVIF interrupt can be generated.

## EXAMPLE 27-1: CLEARING ACTVIF BIT (UIR<2>)

#### Assembly: BCF UCON, SUSPND LOOP: BTFSS UIR, ACTVIF BRA DONE BCF UIR, ACTVIF BRA LOOP DONE:

#### C:

UCONbits.SUSPND = 0; while (UIRbits.ACTVIF) { UIRbits.ACTVIF = 0; }

#### 27.5.2 USB INTERRUPT ENABLE REGISTER (UIE)

The USB Interrupt Enable (UIE) register (Register 27-8) contains the enable bits for the USB status interrupt sources. Setting any of these bits will enable the respective interrupt source in the UIR register.

The values in this register only affect the propagation of an interrupt condition to the microcontroller's interrupt logic. The flag bits are still set by their interrupt conditions, allowing them to be polled and serviced without actually generating an interrupt.

#### Register 27-8: UIE: USB INTERRUPT ENABLE REGISTER

U-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0

bit 1	UERRIE: USB Error Interrupt Enable bit
	1 = USB error interrupt is enabled 0 = USB error interrupt is disabled
bit 0	URSTIE: USB Reset Interrupt Enable bit
	1 = USB Reset interrupt is enabled
	0 = USB Reset interrupt is disabled

#### 27.5.3 USB ERROR INTERRUPT STATUS REGISTER (UEIR)

The USB Error Interrupt STATUS register (Register 27-9) contains the flag bits for each of the error sources within the USB peripheral. Each of these sources is controlled by a corresponding interrupt enable bit in the UEIE register. All of the USB error flags are ORed together to generate the USB Error Interrupt Flag (UERRIF) at the top level of the interrupt logic.

Each error bit is set as soon as the error condition is detected. Thus, the interrupt will typically not correspond with the end of a token being processed.

Once an interrupt bit has been set by the SIE, it must be cleared in software by writing a '0'.

## Register 27-9: UEIR: USB ERROR INTERRUPT STATUS REGISTER (ACCESS F63h)

	0 = The token packet was accepted
bit 0	PIDEF: PID Check Failure Flag bit
	1 = PID check failed
	0 = PID check passed

#### 27.5.4 USB ERROR INTERRUPT ENABLE REGISTER (UEIE)

The USB Error Interrupt Enable register (Register 27-10) contains the enable bits for each of the USB error interrupt sources. Setting any of these bits will enable the respective error interrupt source in the UEIR register to propagate into the UERR bit at the top level of the interrupt logic.

As with the UIE register, the enable bits only affect the propagation of an interrupt condition to the microcontroller's interrupt logic. The flag bits are still set by their interrupt conditions, allowing them to be polled and serviced without actually generating an interrupt.

## 27.6 USB Power Modes

Many USB applications will likely have several different sets of power requirements and configuration. The most common power modes encountered are Bus Power Only, Self-Power Only and Dual Power with Self-Power Dominance. The most common cases are presented here. Also provided is a means of estimating the current consumption of the USB transceiver.

#### 27.6.1 BUS POWER ONLY

In Bus Power Only mode, all power for the application is drawn from the USB (Figure 27-9). This is effectively the simplest power method for the device.

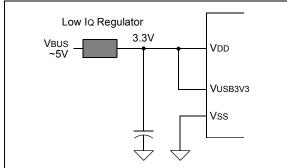

In order to meet the inrush current requirements of the "USB 2.0 Specification", the total effective capacitance appearing across VBUs and ground must be no more than 10  $\mu$ F. If not, some kind of inrush timing is required. For more details, see Section 7.2.4 of the "USB 2.0 Specification".

According to the "USB 2.0 Specification", all USB devices must also support a Low-Power Suspend mode. In the USB Suspend mode, devices must consume no more than 2.5 mA from the 5V VBUS line of the USB cable.

The host signals the USB device to enter the Suspend mode by stopping all USB traffic to that device for more than 3 ms. This condition will cause the IDLEIF bit in the UIR register to become set.

During the USB Suspend mode, the D+ or D- pull-up resistor must remain active, which will consume some of the allowed suspend current: 2.5 mA budget.

## FIGURE 27-9: BUS POWER ONLY

## 27.6.2 SELF-POWER ONLY

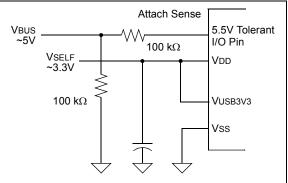

In Self-Power Only mode, the USB application provides its own power, with very little power being pulled from the USB. See Figure 27-10 for an example.

Note that an attach indication is added to indicate when the USB has been connected and the host is actively powering VBUS.

In order to meet compliance specifications, the USB module (and the D+ or D- pull-up resistor) should not be enabled until the host actively drives VBUS high. One of the 5.5V tolerant I/O pins may be used for this purpose.

The application should never source any current onto the 5V VBUS pin of the USB cable.

#### FIGURE 27-10: SELF-POWER ONLY

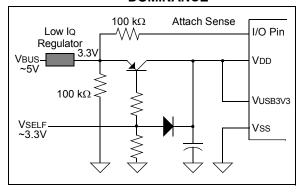

#### 27.6.3 DUAL POWER WITH SELF-POWER DOMINANCE

Some applications may require a dual power option. This allows the application to use internal power primarily, but switch to power from the USB when no internal power is available. See Figure 27-11 for a simple Dual Power with Self-Power Dominance mode example, which automatically switches between Self-Power Only and USB Bus Power Only modes.

Dual power devices must also meet all of the special requirements for inrush current and Suspend mode current, and must not enable the USB module until VBUS is driven high. See Section 27.6.1 "Bus Power Only" and Section 27.6.2 "Self-Power Only" for descriptions of those requirements. Additionally, dual power devices must never source current onto the 5V VBUS pin of the USB cable.

#### FIGURE 27-11: DUAL POWER WITH SELF-POWER DOMINANCE

Note: Users should keep in mind the limits for devices drawing power from the USB. According to USB Specification 2.0, this cannot exceed 100 mA per low-power device or 500 mA per high-power device.

#### 27.6.4 USB TRANSCEIVER CURRENT CONSUMPTION

The USB transceiver consumes a variable amount of current depending on the characteristic impedance of the USB cable, the length of the cable, the VUSB3V3 supply voltage and the actual data patterns moving across the USB cable. Longer cables have larger capacitances and consume more total energy when switching output states.

Data patterns that consist of "IN" traffic consume far more current than "OUT" traffic. IN traffic requires the PIC<sup>®</sup> MCU to drive the USB cable, whereas OUT traffic requires that the host drive the USB cable.

The data that is sent across the USB cable is NRZI encoded. In the NRZI encoding scheme, '0' bits cause a toggling of the output state of the transceiver (either from a "J" state to a "K" state or vise versa). With the exception of the effects of bit stuffing, NRZI encoded '1'

bits do not cause the output state of the transceiver to change. Therefore, IN traffic consisting of data bits of value, '0', cause the most current consumption, as the transceiver must charge/discharge the USB cable in order to change states.

More details about NRZI encoding and bit stuffing can be found in the "*USB 2.0 Specification*", Section 7.1, although knowledge of such details is not required to make USB applications using the PIC18FXXJ94 of microcontrollers. Among other things, the SIE handles bit stuffing/unstuffing, NRZI encoding/decoding and CRC generation/checking in hardware.

The total transceiver current consumption will be application-specific. However, to help estimate how much current actually may be required in full-speed applications, Equation 27-1 can be used.

See Equation 27-2 to know how this equation can be used for a theoretical application.

## EQUATION 27-1: ESTIMATING USB TRANSCEIVER CURRENT CONSUMPTION

IXCVR =	$\frac{(40 \text{ mA} \cdot \text{V}\text{U}\text{s}\text{B}\text{3}\text{V}\text{3} \cdot \text{P}\text{Z}\text{e}\text{r}\text{o} \cdot \text{P}\text{i}\text{N} \cdot \text{L}\text{C}\text{A}\text{B}\text{L}\text{E})}{1 + \text{IPULLUE}}$				
IACVK -	(3.3V • 5m)	+ IPULLUP			

Legend: VUSB3V3 – Voltage applied to the VUSB3V3 pin in volts (should be 3.0V to 3.6V).

PZERO – Percentage (in decimal) of the IN traffic bits sent by the PIC® MCU that are a value of '0'.

PIN – Percentage (in decimal) of total bus bandwidth that is used for IN traffic.

LCABLE – Length (in meters) of the USB cable. The "USB 2.0 Specification" requires that full-speed applications use cables no longer than 5m.

IPULLUP – Current which the nominal, 1.5 k $\Omega$  pull-up resistor (when enabled) must supply to the USB cable. On the host or hub end of the USB cable, 15 k $\Omega$  nominal resistors (14.25 k $\Omega$  to 24.8 k $\Omega$ ) are present which pull both the D+ and D- lines to ground. During bus Idle conditions (such as between packets or during USB Suspend mode), this results in up to 218  $\mu$ A of guiescent current drawn at 3.3V.

IPULLUP is also dependant on bus traffic conditions and can be as high as 2.2 mA when the USB bandwidth is fully utilized (either IN or OUT traffic) for data that drives the lines to the "K" state most of the time.

## EQUATION 27-2: CALCULATING USB TRANSCEIVER CURRENT<sup>†</sup>

For this example, the following assumptions are made about the application:

- 3.3V will be applied to VUSB3V3 and VDD, with the core voltage regulator enabled.
- This is a full-speed application that uses one interrupt IN endpoint that can send one packet of 64 bytes every 1 ms, with no restrictions on the values of the bytes being sent. The application may or may not have additional traffic on OUT endpoints.
- A regular USB "B" or "mini-B" connector will be used on the application circuit board.

In this case, PZERO = 100% = 1, because there should be no restriction on the value of the data moving through the IN endpoint. All 64 kbps of data could potentially be bytes of value, 00h. Since '0' bits cause toggling of the output state of the transceiver, they cause the USB transceiver to consume extra current charging/discharging the cable. In this case, 100% of the data bits sent can be of value '0'. This should be considered the "max" value, as normal data will consist of a fair mix of ones and zeros.

This application uses 64 kbps for IN traffic out of the total bus bandwidth of 1.5 Mbps (12 Mbps), therefore:

Pin = 
$$\frac{64 \text{ kbps}}{1.5 \text{ Mbps}} = 4.3\% = 0.043$$

Since a regular "B" or "mini-B" connector is used in this application, the end user may plug in any type of cable up to the maximum allowed 5m length. Therefore, we use the worst-case length:

LCABLE = 5 meters

Assume IPULLUP = 2.2 mA. The actual value of IPULLUP will likely be closer to 218  $\mu$ A, but allowance for the worst-case. USB bandwidth is shared between all the devices which are plugged into the root port (via hubs). If the application is plugged into a USB 1.1 hub that has other devices plugged into it, your device may see host to device traffic on the bus, even if it is not addressed to your device. Since any traffic, regardless of source, can increase the IPULLUP current above the base 218  $\mu$ A, it is safest to allow for the worst-case of 2.2 mA.

Therefore:

IXCVR = 
$$\frac{(40 \text{ mA} \cdot 3.3 \text{ V} \cdot 1 \cdot 0.043 \cdot 5 \text{m})}{(3.3 \text{ V} \cdot 5 \text{m})} + 2.2 \text{ mA} = 3.9 \text{ mA}$$

† The calculated value should be considered an approximation and additional guardband or applicationspecific product testing is recommended. The transceiver current is "in addition to" the rest of the current consumed by the PIC18FXXJ94 device that is needed to run the core, drive the other I/O lines, power the various modules, etc.

## 27.7 Oscillator

The USB module has specific clock requirements. For full-speed operation, the clock source must be 48 MHz. Even so, the microcontroller core and other peripherals are not required to run at that clock speed.

## 27.8 USB Firmware and Drivers

Microchip provides a number of application-specific resources, such as USB firmware and driver support. Refer to www.microchip.com for the latest firmware and driver support.

 TABLE 27-4:
 REGISTERS ASSOCIATED WITH USB MODULE OPERATION<sup>(1)</sup>

Legend: — = unimplemented, read as '0'. Shaded cells are not used by the USB module.

**Note 1:** This table includes only those hardware mapped SFRs located in Bank 15 of the data memory space. The Buffer Descriptor registers, which are mapped into Bank 4 and are not true SFRs, are listed separately in Table 27-3.

#### 27.9 Overview of USB

This section presents some of the basic USB concepts and useful information necessary to design a USB device. Although much information is provided in this section, there is a plethora of information provided within the USB specifications and class specifications. Thus, the reader is encouraged to refer to the USB specifications for more information (www.usb.org). If you are very familiar with the details of USB, then this section serves as a basic, high-level refresher of USB.

#### 27.9.1 LAYERED FRAMEWORK

USB device functionality is structured into a layered framework, graphically illustrated in Figure 27-12. Each level is associated with a functional level within the device. The highest layer, other than the device, is the configuration. A device may have multiple configurations. For example, a particular device may have multiple power requirements based on Self-Power Only or Bus Power Only modes.

For each configuration, there may be multiple interfaces. Each interface could support a particular mode of that configuration.

Below the interface is the endpoint(s). Data is directly moved at this level. There can be as many as 16 bidirectional endpoints. Endpoint 0 is always a control endpoint, and by default, when the device is on the bus, Endpoint 0 must be available to configure the device.

#### 27.9.2 FRAMES

Information communicated on the bus is grouped into 1 ms time slots, referred to as frames. Each frame can contain many transactions to various devices and endpoints. See Figure 27-8 for an example of a transaction within a frame.

#### 27.9.3 TRANSFERS

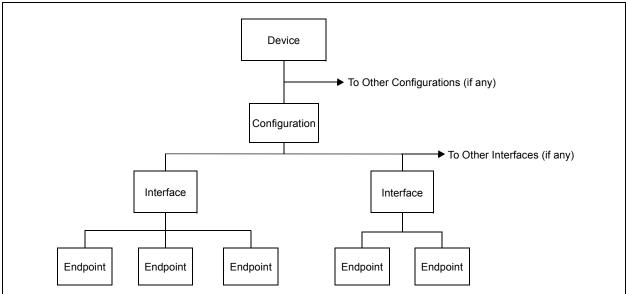

There are four transfer types defined in the USB specification.

- **Isochronous:** This type provides a transfer method for large amounts of data (up to 1023 bytes) with timely delivery ensured; however, the data integrity is not ensured. This is good for streaming applications where small data loss is not critical, such as audio.
- **Bulk:** This type of transfer method allows for large amounts of data to be transferred with ensured data integrity; however, the delivery timeliness is not ensured.
- **Interrupt:** This type of transfer provides for ensured timely delivery for small blocks of data, plus data integrity is ensured.
- **Control:** This type provides for device setup control.

While full-speed devices support all transfer types, lowspeed devices are limited to interrupt and control transfers only.

#### 27.9.4 POWER

Power is available from the USB. The USB specification defines the bus power requirements. Devices may either be self-powered or bus-powered. Self-powered devices draw power from an external source, while bus-powered devices use power supplied from the bus.

#### FIGURE 27-12: USB LAYERS

The USB Specification limits the power taken from the bus. Each device is ensured 100 mA at approximately 5V (one unit load). Additional power may be requested, up to a maximum of 500 mA.

Note that power above one unit load is a request and the host or hub is not obligated to provide the extra current. Thus, a device capable of consuming more than one unit load must be able to maintain a low-power configuration of a one unit load or less, if necessary.

The USB Specification also defines a Suspend mode. In this situation, current must be limited to 500  $\mu$ A, averaged over one second. A device must enter a suspend state after 3 ms of inactivity (i.e., no SOF tokens for 3 ms). A device entering Suspend mode must drop current consumption within 10 ms after suspend. Likewise, when signaling a wake-up, the device must signal a wake-up within 10 ms of drawing current above the suspend limit.

#### 27.9.5 ENUMERATION

When the device is initially attached to the bus, the host enters an enumeration process in an attempt to identify the device. Essentially, the host interrogates the device, gathering information, such as power consumption, data rates and sizes, protocol and other descriptive information; descriptors contain this information. A typical enumeration process would be as follows:

- 1. USB Reset Reset the device. Thus, the device is not configured and does not have an address (Address 0).
- 2. Get Device Descriptor The host requests a small portion of the device descriptor.
- 3. USB Reset Reset the device again.
- 4. Set Address The host assigns an address to the device.
- 5. Get Device Descriptor The host retrieves the device descriptor, gathering info, such as manufacturer, type of device, maximum control packet size.
- 6. Get configuration descriptors.
- 7. Get any other descriptors.
- 8. Set a configuration.

The exact enumeration process depends on the host.

#### 27.9.6 DESCRIPTORS

There are eight different standard descriptor types, of which, five are most important for this device.

#### 27.9.6.1 Device Descriptor

The device descriptor provides general information, such as manufacturer, product number, serial number, the class of the device and the number of configurations. There is only one device descriptor.

#### 27.9.6.2 Configuration Descriptor

The configuration descriptor provides information on the power requirements of the device and how many different interfaces are supported when in this configuration. There may be more than one configuration for a device (i.e., low-power and high-power configurations).

#### 27.9.6.3 Interface Descriptor

The interface descriptor details the number of endpoints used in this interface, as well as the class of the interface. There may be more than one interface for a configuration.

#### 27.9.6.4 Endpoint Descriptor

The endpoint descriptor identifies the transfer type (Section 27.9.3 "Transfers") and direction, and some other specifics for the endpoint. There may be many endpoints in a device and endpoints may be shared in different configurations.

#### 27.9.6.5 String Descriptor

Many of the previous descriptors reference one or more string descriptors. String descriptors provide human readable information about the layer (Section 27.9.1 "Layered Framework") they describe. Often these strings show up in the host to help the user identify the device. String descriptors are generally optional to save memory and are encoded in a unicode format.

#### 27.9.7 BUS SPEED

Each USB device must indicate its bus presence and speed to the host. This is accomplished through a  $1.5 \text{ k}\Omega$  resistor, which is connected to the bus at the time of the attachment event.

Depending on the speed of the device, the resistor either pulls up the D+ or D- line to 3.3V. For a lowspeed device, the pull-up resistor is connected to the D- line. For a full-speed device, the pull-up resistor is connected to the D+ line.

### 27.9.8 CLASS SPECIFICATIONS AND DRIVERS

USB specifications include class specifications, which operating system vendors optionally support. Examples of classes include: Audio, Mass Storage, Communications and Human Interface (HID). In most cases, a driver is required at the host side to 'talk' to the USB device. In custom applications, a driver may need to be developed. Fortunately, drivers are available for most common host systems for the most common classes of devices. Thus, these drivers can be reused.

#### 28.0 SPECIAL FEATURES OF THE CPU

The PIC18FXXJ94 of devices includes several features intended to maximize reliability and minimize cost through elimination of external components. These include:

- Oscillator Selection
- · Resets:
  - Power-on Reset (POR)
  - Power-up Timer (PWRT)
  - Oscillator Start-up Timer (OST)
- Brown-out Reset (BOR)
- Interrupts
- · Watchdog Timer (WDT) and On-chip Regulator
- Fail-Safe Clock Monitor
- · Two-Speed Start-up
- Code Protection
- ID Locations
- In-Circuit Serial Programming™

The oscillator can be configured for the application depending on frequency, power, accuracy and cost. All of the options are discussed in detail in **Section 3.0 "Oscillator Configurations"**.

A complete discussion of device Resets and interrupts is available in previous sections of this data sheet.

In addition to their Power-up and Oscillator Start-up Timers provided for Resets, the PIC18FXXJ94 of devices has a Watchdog Timer, which is either permanently enabled via the Configuration bits or software controlled (if configured as disabled).

The inclusion of an internal RC Oscillator (LF-INTOSC) also provides the additional benefits of a Fail-Safe Clock Monitor (FSCM) and Two-Speed Start-up. FSCM provides for background monitoring of the peripheral clock and automatic switchover in the event of its failure. Two-Speed Start-up enables code to be executed almost immediately on start-up, while the primary clock source completes its start-up delays.

All of these features are enabled and configured by setting the appropriate Configuration register bits.

#### 28.1 Configuration Bits

Devices of the PIC18FXXJ94 do not use persistent memory registers to store configuration information. The Configuration registers, CONFIG1L through CON-FIG8H, are implemented as volatile memory. Immediately after power-up, or after a device Reset, the microcontroller hardware automatically loads the CON-FIG1L through CONFIG8H registers with configuration data stored in nonvolatile Flash program memory. The last eight words of Flash program memory, known as the Flash Configuration Words (FCW), are used to store the configuration data.

Table 28-2 provides the Flash program memory, which will be loaded into the corresponding Configuration register.

When creating applications for these devices, users should always specifically allocate the location of the FCW for configuration data. This is to make certain that program code is not stored in this address when the code is compiled.

The four Most Significant bits (MSb) of the FCW, corresponding to CONFIG1H, CONFIG2H, CONFIG3H, CONFIG4H, CONFIG5H, CONFIG6H, CONFIG7H and CONFIG8H, should always be programmed to '1111'.

This makes these FCWs appear to be NOP instructions in the remote event that their locations are ever executed by accident.

The four MSbs of the CONFIG1H, CONFIG2H, CON-FIG3H, CONFIG4H CONFIG5H, CONFIG6H, CON-FIG7H and CONFIG8H, registers are not implemented, so writing '1's to their corresponding FCW has no effect on device operation.

To prevent inadvertent configuration changes during code execution, the Configuration registers, CONFIG1L through CONFIG8H, are loaded only once per power-up or Reset cycle. User's firmware can still change the configuration by using self-reprogramming to modify the contents of the FCW.

Modifying the FCW will not change the active contents being used in the CONFIG1L through CONFIG8H registers until after the device is reset.

### TABLE 28-1:MAPPING OF THE FLASH CONFIGURATION WORDS TO THE CONFIGURATION<br/>REGISTERS

Configuration Register (Volatile)	Configuration Register Address	Flash Configuration Byte Address
CONFIG1L	300000h	XXXF0h

	101 =Low-Power RC Oscillator (LPRC) 110 =Fast RC Oscillator (FRC) divided by 16 (500 kHz)
	111 =Fast RC Oscillator with divide-by-N (FRCDIV)
Note 1:	The CONFIG2L bits can only be programmed indirectly by programming the Flash Configuration Word.
•	

- 2: The CONFIG2L is reset to '1' only on VDD Reset; it is reloaded with the programmed value at any device Reset.
- **3:** Although CONFIG2L is reset to '1' only on VDD Reset, these values are not used until after the actual configuration values are read out and stored in the register bits. Therefore, for these bits, the Reset value has no effect on the operation of the system.
- 4: Unlike other Configuration registers, the CLKOEN holding register is reset to a '0' on any VDD Reset. This prevents the CLKO pin from driving until the actual configuration values are read out and stored in the register.

0110	0100	000 = PIC18F65J94

bit 4-0 **REV<4:0>:** Revision ID bits

These bits are used to indicate the device revision.

#### 28.2 Watchdog Timer (WDT)

For the PIC18FXXJ94 of devices, the WDT is driven by the LF-INTOSC source. When the WDT is enabled, the clock source is also enabled. The nominal WDT period is 4 ms and has the same stability as the LF-INTOSC Oscillator.

The 4 ms period of the WDT is multiplied by a 16-bit postscaler. Any output of the WDT postscaler is selected by a multiplexer, controlled by bits in Configuration Register 2H. Available periods range from 4 ms to 4,194 seconds (about one hour). The WDT and postscaler are cleared when any of the following events occur: a SLEEP or CLRWDT instruction is executed, the IRCFx bits (OSCCON3<2:0>) are changed or a clock failure has occurred.

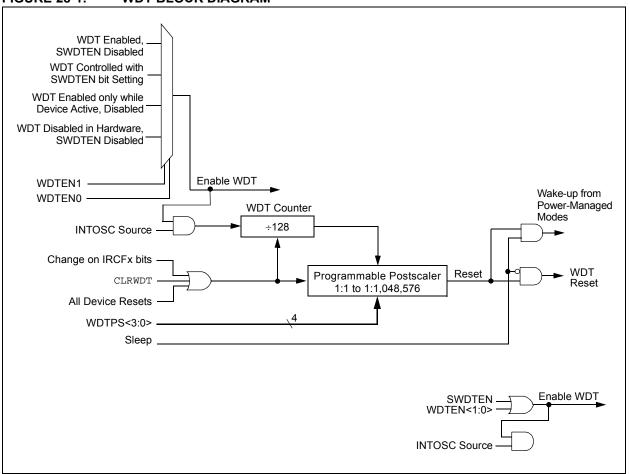

#### WINDOWED OPERATION 28.2.1

The Watchdog Timer has an optional Fixed Window mode of operation. In this Windowed mode, CLRWDT instructions can only reset the WDT during the last 1/4 of the programmed WDT period. A CLRWDT instruction executed before that window causes a WDT Reset, similar to a WDT time-out.

**FIGURE 28-1:** WDT BLOCK DIAGRAM Windowed WDT mode is enabled by programming the WINDIS Configuration bit (CONFIG6H<2>) to '0'.

The WDT can be operated in one of four modes, as determined by WDTEN<1:0> (CONFIG6H<1:0>. The four modes are:

- WDT Enabled
- WDT Disabled
- WDT under Software Control. SWDTEN (RCON2<5>)
- WDT:
  - Enabled during normal operation
  - Disabled during Sleep
  - Note 1: The CLRWDT and SLEEP instructions clear the WDT and postscaler counts when executed.
    - **2:** Changing the setting of the IRCFx bits (OSCCON3<2:0>) clear the WDT and postscaler counts.
    - 3: When a CLRWDT instruction is executed, the postscaler count will be cleared.

#### 28.2.2 CONTROL REGISTER

Register 28-17 shows the RCON2 register. This is a readable and writable register which contains a control bit that allows software to override the WDT Enable Configuration bit, but only if the Configuration bit has disabled the WDT.

#### 28.3 Two-Speed Start-up

The Two-Speed Start-up feature helps to minimize the latency period from oscillator start-up to code execution by allowing the microcontroller to use the INTOSC (LF-INTOSC, MF-INTOSC, HF-INTOSC) Oscillator as a clock source until the primary clock source is available. It is enabled by setting the IESO Configuration bit.

Two-Speed Start-up should be enabled only if the Primary Oscillator mode is LP, MS or HS (Crystal-Based modes). Other sources do not require an OST start-up delay; for these, Two-Speed Start-up should be disabled.

When enabled, Resets and wake-ups from Sleep mode cause the device to configure itself to run from the internal oscillator block as the clock source, following the time-out of the Power-up Timer (PWRT) after a Poweron Reset is enabled. This allows almost immediate code execution while the Primary Oscillator starts and the OST is running. Once the OST times out, the device automatically switches to PRI\_RUN mode.

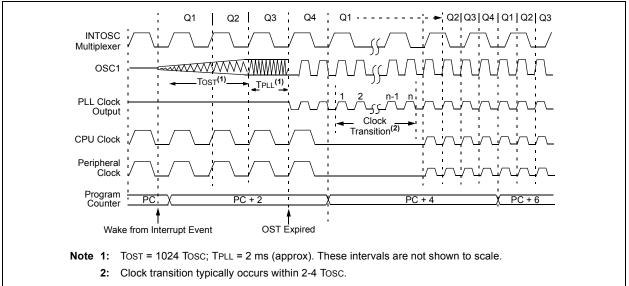

To use a higher clock speed on wake-up, the INTOSC or postscaler clock sources can be selected to provide a higher clock speed by setting bits, IRCF<2:0>, immediately after Reset. For wake-ups from Sleep, the INTOSC or postscaler clock sources can be selected by setting the IRCF2:0> bits prior to entering Sleep mode. In all other power-managed modes, Two-Speed Start-up is not used. The device will be clocked by the currently selected clock source until the primary clock source becomes available. The setting of the IESO Configuration bit is ignored.

#### 28.3.1 SPECIAL CONSIDERATIONS FOR USING TWO-SPEED START-UP

While using the INTOSC Oscillator in Two-Speed Startup, the device still obeys the normal command sequences for entering power-managed modes, including multiple SLEEP instructions. In practice, this means that user code can change the NOSC<2:0> bit settings or issue SLEEP instructions before the OST times out. This would allow an application to briefly wake-up, perform routine "housekeeping" tasks and return to Sleep before the device starts to operate from the Primary Oscillator.

User code can also check if the primary clock source is currently providing the device clocking by checking the status of the COSC<2:0> bits (OSCCON<2:0>). If the bit is set, the Primary Oscillator is providing the clock. Otherwise, the internal oscillator block is providing the clock during wake-up from Reset or Sleep mode.

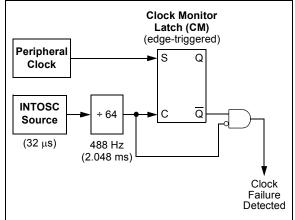

#### 28.4 Fail-Safe Clock Monitor

The Fail-Safe Clock Monitor (FSCM) allows the microcontroller to continue operation in the event of an external oscillator failure by automatically switching the device clock to the internal oscillator block. The FSCM function is enabled by clearing the FSCMx Configuration bits.

When FSCM is enabled, the LF-INTOSC Oscillator runs at all times to monitor clocks to peripherals and provides a backup clock in the event of a clock failure. Clock monitoring (shown in Figure 28-3) is accomplished by creating a sample clock signal, which is the output from the LF-INTOSC, divided by 64. This allows ample time between FSCM sample clocks for a peripheral clock edge to occur. The peripheral device clock and the sample clock are presented as inputs to the Clock Monitor (CM) latch. The CM is set on the falling edge of the device clock source, but cleared on the rising edge of the sample clock.

Clock failure is tested for on the falling edge of the sample clock. If a sample clock falling edge occurs while CM is still set, a clock failure has been detected (Figure 28-4). This causes the following:

- The FSCM generates an oscillator fail interrupt by setting bit, OSCFIF (PIR2<7>)
- The device clock source switches to the internal oscillator block (OSCCON is not updated to show the current clock source – this is the fail-safe condition)
- The WDT is reset

During switchover, the postscaler frequency from the internal oscillator block may not be sufficiently stable for timing-sensitive applications. In these cases, it may be desirable to select another clock configuration and enter an alternate power-managed mode. This can be done to attempt a partial recovery or execute a controlled shutdown. See Section 28.3.1 "Special Considerations for Using Two-Speed Start-up" for more details.

To use a higher clock speed on wake-up, the INTOSC or postscaler clock sources can be selected to provide a higher clock speed by setting bits, IRCF<2:0>, immediately after Reset. For wake-ups from Sleep, the INTOSC or postscaler clock sources can be selected by setting the IRCF<2:0> bits prior to entering Sleep mode.

The FSCM will detect only failures of the primary or secondary clock sources. If the internal oscillator block fails, no failure would be detected nor would any action be possible.

#### 28.4.1 FSCM AND THE WATCHDOG TIMER

Both the FSCM and the WDT are clocked by the INTOSC Oscillator. Since the WDT operates with a separate divider and counter, disabling the WDT has no effect on the operation of the INTOSC Oscillator when the FSCM is enabled.

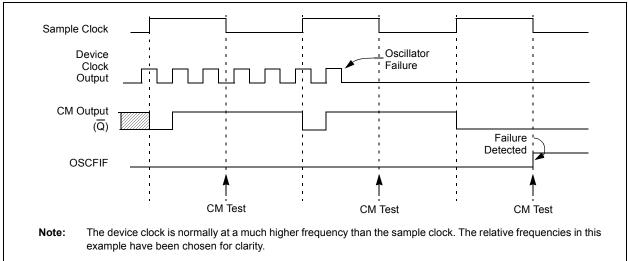

As already noted, the clock source is switched to the INTOSC clock when a clock failure is detected. Depending on the frequency selected by the IRCF<2:0> bits, this may mean a substantial change in the speed of code execution. If the WDT is enabled with a small prescale value, a decrease in clock speed allows a WDT time-out to occur and a subsequent device Reset. For this reason, Fail-Safe Clock events also reset the WDT and postscaler, allowing it to start timing from when execution speed was changed and decreasing the likelihood of an erroneous time-out.

#### 28.4.2 EXITING FAIL-SAFE OPERATION

The Fail-Safe condition is terminated by either a device Reset or by entering a power-managed mode. On Reset, the controller starts the primary clock source, specified in Configuration Register 1H (with any required start-up delays that are required for the oscillator mode, such as the OST or PLL timer). The INTOSC multiplexer provides the device clock until the primary clock source becomes ready (similar to a Two-Speed Start-up). The clock source is then switched to the primary clock automatically after an OST. The Fail-Safe Clock Monitor then resumes monitoring the peripheral clock.

The primary clock source may never become ready during start-up. In this case, operation is clocked by the INTOSC multiplexer. The OSCCON register will remain in its Reset state until a power-managed mode is entered.

#### 28.4.3 FSCM INTERRUPTS IN POWER-MANAGED MODES

By entering a power-managed mode, the clock multiplexer selects the clock source selected by the OSCCON register. Fail-Safe Clock Monitoring of the powermanaged clock source resumes in the power-managed mode.

If an oscillator failure occurs during power-managed operation, the subsequent events depend on whether or not the oscillator failure interrupt is enabled. If enabled (OSCFIF = 1), code execution will be clocked by the INTOSC multiplexer. An automatic transition back to the failed clock source will not occur.

If the interrupt is disabled, subsequent interrupts while in Idle mode will cause the CPU to begin executing instructions while being clocked by the INTOSC source.

#### 28.4.4 POR OR WAKE FROM SLEEP

The FSCM is designed to detect oscillator failure at any point after the device has exited Power-on Reset (POR) or low-power Sleep mode. When the primary device clock is EC, RC or INTOSC modes, monitoring can begin immediately following these events. For oscillator modes involving a crystal or resonator (HS, HSPLL, LP or MS), the situation is somewhat different. Since the oscillator may require a start-up time considerably longer than the FCSM sample clock time, a false clock failure may be detected. To prevent this, the internal oscillator block is automatically configured as the device clock and functions until the primary clock is stable (when the OST and PLL timers have timed out).

This is identical to Two-Speed Start-up mode. Once the primary clock is stable, the INTOSC returns to its role as the FSCM source.

Note: The same logic that prevents false oscillator failure interrupts on POR, or wake from Sleep, also prevents the detection of the oscillator's failure to start at all following these events. This is avoided by an OST time-out condition and by using a timing routine to determine if the oscillator is taking too long to start. Even so, no oscillator failure interrupt will be flagged.

As noted in Section 28.3.1 "Special Considerations for Using Two-Speed Start-up", it is also possible to select another clock configuration and enter an alternate power-managed mode while waiting for the primary clock to become stable. When the new powermanaged mode is selected, the primary clock is disabled.

### 28.4.5 PROGRAM VERIFICATION AND CODE PROTECTION

For all devices in the PIC18FXXJ94 of devices, the onchip program memory space is treated as a single block. Code protection for this block is controlled by one Configuration bit, CP0. This bit inhibits external reads and writes to the program memory space. It has no direct effect in normal execution mode.

#### 28.4.6 CONFIGURATION REGISTER PROTECTION

The Configuration registers are protected against untoward changes or reads in two ways. The primary protection is the write-once feature of the Configuration bits, which prevents reconfiguration once the bit has been programmed during a power cycle. To safeguard against unpredictable events, Configuration bit changes, resulting from individual cell level disruptions (such as ESD events), will cause a parity error and trigger a device Reset. This is seen by the user as a Configuration Mismatch (CM) Reset.

The data for the Configuration registers is derived from the FCW in program memory. When the CP0 bit is set, the source data for device configuration is also protected as a consequence.

#### 28.5 In-Circuit Serial Programming

The PIC18FXXJ94 of devices can be serially programmed while in the end application circuit. This is simply done with two lines for clock and data and three other lines for power, ground and the programming voltage. This allows customers to manufacture boards with unprogrammed devices and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

For the various programming modes, see the programming specification

#### 28.6 In-Circuit Debugger

When the DEBUG Configuration bit is programmed to a '0', the In-Circuit Debugger functionality is enabled. This function allows simple debugging functions when used with MPLAB<sup>®</sup> IDE. When the microcontroller has this feature enabled, some resources are not available for general use. Table 28-3 shows which resources are required by the background debugger.

TABLE 28-3:	DEBUGGER RESOURCES
-------------	--------------------

I/O Pins:	RB6, RB7
Stack:	Two levels
Program Memory:	512 bytes
Data Memory:	10 bytes

To use the In-Circuit Debugger function of the microcontroller, the design must implement In-Circuit Serial Programming connections to MCLR, VDD, VSS, RB7 and RB6. This will interface to the In-Circuit Debugger module available from Microchip or one of the third-party development tool companies.

### 29.0 INSTRUCTION SET SUMMARY

The PIC18FXXJ94 of devices incorporates the standard set of 75 PIC18 core instructions, as well as an extended set of eight new instructions for the optimization of code that is recursive or that utilizes a software stack. The extended set is discussed later in this section.

#### 29.1 Standard Instruction Set

The standard PIC18 MCU instruction set adds many enhancements to the previous PIC<sup>®</sup> MCU instruction sets, while maintaining an easy migration from these PIC MCU instruction sets. Most instructions are a single program memory word (16 bits), but there are four instructions that require two program memory locations.

Each single-word instruction is a 16-bit word divided into an opcode, which specifies the instruction type and one or more operands, which further specify the operation of the instruction.

The instruction set is highly orthogonal and is grouped into four basic categories:

- Byte-oriented operations
- Bit-oriented operations
- · Literal operations
- Control operations

The PIC18 instruction set summary in Table 29-2 lists **byte-oriented**, **bit-oriented**, **literal** and **control** operations. Table 29-1 shows the opcode field descriptions.

Most byte-oriented instructions have three operands:

- 1. The file register (specified by 'f')
- 2. The destination of the result (specified by 'd')
- 3. The accessed memory (specified by 'a')

The file register designator, 'f', specifies which file register is to be used by the instruction. The destination designator, 'd', specifies where the result of the operation is to be placed. If 'd' is zero, the result is placed in the WREG register. If 'd' is one, the result is placed in the file register specified in the instruction.

All **bit-oriented** instructions have three operands:

- 1. The file register (specified by 'f')
- 2. The bit in the file register (specified by 'b')
- 3. The accessed memory (specified by 'a')

The bit field designator, 'b', selects the number of the bit affected by the operation, while the file register designator, 'f', represents the number of the file in which the bit is located. The **literal** instructions may use some of the following operands:

- A literal value to be loaded into a file register (specified by 'k')
- The desired FSR register to load the literal value into (specified by 'f')
- No operand required (specified by '—')

The **control** instructions may use some of the following operands:

- A program memory address (specified by 'n')
- The mode of the CALL or RETURN instructions (specified by 's')
- The mode of the table read and table write instructions (specified by 'm')
- No operand required (specified by '—')

All instructions are a single word, except for four double-word instructions. These instructions were made double-word to contain the required information in 32 bits. In the second word, the 4 MSbs are '1's. If this second word is executed as an instruction (by itself), it will execute as a NOP.

All single-word instructions are executed in a single instruction cycle, unless a conditional test is true or the Program Counter is changed as a result of the instruction. In these cases, the execution takes two instruction cycles with the additional instruction cycle(s) executed as a NOP.

The double-word instructions execute in two instruction cycles.

One instruction cycle consists of four oscillator periods. Thus, for an oscillator frequency of 4 MHz, the normal instruction execution time is 1  $\mu$ s. If a conditional test is true, or the Program Counter is changed as a result of an instruction, the instruction execution time is 2  $\mu$ s. Two-word branch instructions (if true) would take 3  $\mu$ s.

Figure 29-1 shows the general formats that the instructions can have. All examples use the convention 'nnh' to represent a hexadecimal number.

The Instruction Set Summary, shown in Table 29-2, lists the standard instructions recognized by the Microchip MPASM<sup>™</sup> Assembler.

Section 29.1.1 "Standard Instruction Set" provides a description of each instruction.

#### TABLE 29-1: OPCODE FIELD DESCRIPTIONS

Field	Description
a	RAM access bit:
	a = 0: RAM location in Access RAM (BSR register is ignored)
	a = 1: RAM bank is specified by BSR register
bbb	Bit address within an 8-bit file register (0 to 7).
BSR	Bank Select Register. Used to select the current RAM bank.
C, DC, Z, OV, N	ALU Status bits: Carry, Digit Carry, Zero, Overflow, Negative.
d	Destination select bit:
	d = 0: store result in WREG
dt	d = 1: store result in file register f
dest	Destination: either the WREG register or the specified register file location. 8-bit register file address (00h to FFh), or 2-bit FSR designator (0h to 3h).
f	
fs	12-bit register file address (000h to FFFh). This is the source address.
f <sub>d</sub>	12-bit register file address (000h to FFFh). This is the destination address.
GIE	Global Interrupt Enable bit.
k	Literal field, constant data or label (may be either an 8-bit, 12-bit or a 20-bit value).
label	Label name.
mm	The mode of the TBLPTR register for the table read and table write instructions. Only used with table read and table write instructions:
*	No Change to register (such as TBLPTR with table reads and writes)
*+	
*-	Post-Increment register (such as TBLPTR with table reads and writes)
*- +*	Post-Decrement register (such as TBLPTR with table reads and writes)
	Pre-Increment register (such as TBLPTR with table reads and writes) The relative address (2's complement number) for relative branch instructions or the direct address for Call/
n	Branch and Return instructions.
PC	Program Counter.
PCL	Program Counter Low Byte.
PCH	Program Counter High Byte.
PCLATH	Program Counter High Byte Latch.
PCLATU	Program Counter Upper Byte Latch.
PD	Power-Down bit.
PRODH	Product of Multiply High Byte.
PRODL	Product of Multiply Low Byte.
s	Fast Call/Return mode select bit:
2	s = 0: do not update into/from shadow registers
	s = 1: certain registers loaded into/from shadow registers (Fast mode)
TBLPTR	21-bit Table Pointer (points to a Program Memory location).
TABLAT	8-bit Table Latch.
TO	Time-out bit.
TOS	Top-of-Stack.
u	Unused or Unchanged.
WDT	Watchdog Timer.
WREG	Working register (accumulator).
х	Don't care ('0' or '1'). The assembler will generate code with $x = 0$ . It is the recommended form of use for
	compatibility with all Microchip software tools.
Zs	7-bit offset value for Indirect Addressing of register files (source).
zd	7-bit offset value for Indirect Addressing of register files (destination).
{ }	Optional argument.
[text]	Indicates an Indexed Address.
(text)	The contents of text.
[expr] <n></n>	Specifies bit n of the register indicated by the pointer expr.
$\rightarrow$	Assigned to.
< >	Register bit field.
E	In the set of.
italics	User-defined term (font is Courier New).

Byte-oriented file register operations	Example Instruction
<u>15 10 9 8 7 0</u>	
OPCODE d a f (FILE #)	ADDWF MYREG, W, B
<ul> <li>d = 0 for result destination to be WREG register</li> <li>d = 1 for result destination to be file register (f)</li> <li>a = 0 to force Access Bank</li> <li>a = 1 for BSR to select bank</li> <li>f = 8-bit file register address</li> </ul>	
Byte to Byte move operations (2-word)	
<u>15 12 11 0</u>	
OPCODE f (Source FILE #)	MOVFF MYREG1, MYREG2
15 12 11 0	
1111 f (Destination FILE #)	
f = 12-bit file register address	
Bit-oriented file register operations	
<u>15 12 11 9 8 7 0</u>	
OPCODE b (BIT #) a f (FILE #)	BSF MYREG, bit, B
<ul> <li>b = 3-bit position of bit in file register (f)</li> <li>a = 0 to force Access Bank</li> <li>a = 1 for BSR to select bank</li> <li>f = 8-bit file register address</li> </ul>	
Literal operations	
15 8 7 0	
OPCODE k (literal)	MOVLW 7Fh
k = 8-bit immediate value	
Control exerctions	
Control operations	
CALL, GOTO and Branch operations 15 8 7 0	
OPCODE n<7:0> (literal)	GOTO Label
15 12 11 0	
1111 n<19:8> (literal)	
n = 20-bit immediate value	
15 8 7 0	
OPCODE S n<7:0> (literal)	CALL MYFUNC
15 12 11 0	
1111 n<19:8> (literal)	
S = Fast bit	
15 11 10 0	
15 11 10 0 OPCODE n<10:0> (literal)	BRA MYFUNC
	DIA HIFONC
15 8 7 0	
OPCODE n<7:0> (literal)	BC MYFUNC

	,	Exclusive OR WREG with f	1			ffff	ffff		,
Noto 1:		POPT register is modified as a f	-						

**Note 1:** When a PORT register is modified as a function of itself (e.g., MOVF PORTB, 1, 0), the value used will be that value present on the pins themselves. For example, if the data latch is '1' for a pin configured as input and is driven low by an external device, the data will be written back with a '0'.

2: If this instruction is executed on the TMR0 register (and where applicable, d = 1), the prescaler will be cleared if assigned.

**3:** If the Program Counter (PC) is modified or a conditional test is true, the instruction requires two cycles. The second cycle is executed as a NOP.

4: Some instructions are two-word instructions. The second word of these instructions will be executed as a NOP unless the first word of the instruction retrieves the information embedded in these 16 bits. This ensures that all program memory locations have a valid instruction.

#### 29.2 Extended Instruction Set

In addition to the standard 75 instructions of the PIC18 instruction set, the PIC18FXXJ94 of devices also provides an optional extension to the core CPU functionality. The added features include eight additional instructions that augment Indirect and Indexed Addressing operations and the implementation of Indexed Literal Offset Addressing for many of the standard PIC18 instructions.

The additional features of the extended instruction set are enabled by default on unprogrammed devices. Users must properly set or clear the XINST Configuration bit during programming to enable or disable these features.

The instructions in the extended set can all be classified as literal operations, which either manipulate the File Select Registers, or use them for Indexed Addressing. Two of the instructions, ADDFSR and SUBFSR, each have an additional special instantiation for using FSR2. These versions (ADDULNK and SUBULNK) allow for automatic return after execution.

The extended instructions are specifically implemented to optimize re-entrant program code (that is, code that is recursive or that uses a software stack) written in high-level languages, particularly C. Among other things, they allow users working in high-level languages to perform certain operations on data structures more efficiently. These include:

- Dynamic allocation and deallocation of software stack space when entering and leaving subroutines
- Function Pointer invocation
- Software Stack Pointer manipulation
- Manipulation of variables located in a software stack

A summary of the instructions in the extended instruction set is provided in Table 29-3. Detailed descriptions are provided in Section 29.2.2 "Extended Instruction Set". The opcode field descriptions in Table 29-1 (page 566) apply to both the standard and extended PIC18 instruction sets.

Note: The instruction set extension and the Indexed Literal Offset Addressing mode were designed for optimizing applications written in C; the user may likely never use these instructions directly in assembler. The syntax for these commands is provided as a reference for users who may be reviewing code that has been generated by a compiler.

#### 29.2.1 EXTENDED INSTRUCTION SYNTAX

Most of the extended instructions use indexed arguments, using one of the File Select Registers and some offset to specify a source or destination register. When an argument for an instruction serves as part of Indexed Addressing, it is enclosed in square brackets ("[]"). This is done to indicate that the argument is used as an index or offset. The MPASM<sup>™</sup> Assembler will flag an error if it determines that an index or offset value is not bracketed.

When the extended instruction set is enabled, brackets are also used to indicate index arguments in byteoriented and bit-oriented instructions. This is in addition to other changes in their syntax. For more details, see Section 29.2.3.1 "Extended Instruction Syntax with Standard PIC18 Commands".

**Note:** In the past, square brackets have been used to denote optional arguments in the PIC18 and earlier instruction sets. In this text and going forward, optional arguments are denoted by braces ("{ }").

Mnemonic,		Description	Cycles	16-Bit Instruction Word				Status

#### 29.2.3 BYTE-ORIENTED AND BIT-ORIENTED INSTRUCTIONS IN INDEXED LITERAL OFFSET MODE

Note:	Enabling the PIC18 instruction set exten-
	sion may cause legacy applications to
	behave erratically or fail entirely.

In addition to eight new commands in the extended set, enabling the extended instruction set also enables Indexed Literal Offset Addressing (Section 6.6.1 "Indexed Addressing with Literal Offset"). This has a significant impact on the way that many commands of the standard PIC18 instruction set are interpreted.

When the extended set is disabled, addresses embedded in opcodes are treated as literal memory locations: either as a location in the Access Bank (a = 0) or in a GPR bank designated by the BSR (a = 1). When the extended instruction set is enabled and a = 0, however, a file register argument of 5Fh or less is interpreted as an offset from the pointer value in FSR2 and not as a literal address. For practical purposes, this means that all instructions that use the Access RAM bit as an argument – that is, all byte-oriented and bit-oriented instructions, or almost half of the core PIC18 instructions – may behave differently when the extended instruction set is enabled.

When the content of FSR2 is 00h, the boundaries of the Access RAM are essentially remapped to their original values. This may be useful in creating backward compatible code. If this technique is used, it may be necessary to save the value of FSR2 and restore it when moving back and forth between C and assembly routines in order to preserve the Stack Pointer. Users must also keep in mind the syntax requirements of the extended instruction set (see Section 29.2.3.1 "Extended Instruction Syntax with Standard PIC18 Commands").

Although the Indexed Literal Offset mode can be very useful for dynamic stack and pointer manipulation, it can also be very annoying if a simple arithmetic operation is carried out on the wrong register. Users who are accustomed to the PIC18 programming must keep in mind, that when the extended instruction set is enabled, register addresses of 5Fh or less are used for Indexed Literal Offset Addressing.

Representative examples of typical byte-oriented and bit-oriented instructions in the Indexed Literal Offset mode are provided on the following page to show how execution is affected. The operand conditions shown in the examples are applicable to all instructions of these types.

#### 29.2.3.1 Extended Instruction Syntax with Standard PIC18 Commands

When the extended instruction set is enabled, the file register argument 'f' in the standard byte-oriented and bit-oriented commands is replaced with the literal offset value 'k'. As already noted, this occurs only when 'f' is less than or equal to 5Fh. When an offset value is used, it must be indicated by square brackets ("[]"). As with the extended instructions, the use of brackets indicates to the compiler that the value is to be interpreted as an index or an offset. Omitting the brackets, or using a value greater than 5Fh within the brackets, will generate an error in the MPASM<sup>™</sup> Assembler.

If the index argument is properly bracketed for Indexed Literal Offset Addressing, the Access RAM argument is never specified; it will automatically be assumed to be '0'. This is in contrast to standard operation (extended instruction set disabled), when 'a' is set on the basis of the target address. Declaring the Access RAM bit in this mode will also generate an error in the MPASM Assembler.

The destination argument, 'd', functions as before.

In the latest versions of the MPASM Assembler, language support for the extended instruction set must be explicitly invoked. This is done with either the command-line option,  $/_{Y}$ , or the PE directive in the source listing.

#### 29.2.4 CONSIDERATIONS WHEN ENABLING THE EXTENDED INSTRUCTION SET

It is important to note that the extensions to the instruction set may not be beneficial to all users. In particular, users who are not writing code that uses a software stack may not benefit from using the extensions to the instruction set.

Additionally, the Indexed Literal Offset Addressing mode may create issues with legacy applications written to the PIC18 assembler. This is because instructions in the legacy code may attempt to address registers in the Access Bank below 5Fh. Since these addresses are interpreted as literal offsets to FSR2 when the instruction set extension is enabled, the application may read or write to the wrong data addresses.

When porting an application to the PIC18FXXJ94, it is very important to consider the type of code. A large, reentrant application that is written in C and would benefit from efficient compilation will do well when using the instruction set extensions. Legacy applications that heavily use the Access Bank will most likely not benefit from using the extended instruction set.

ADDWF	ADD W to Indexed (Indexed Literal Offset mode)			
Syntax:	ADDWF	[k] {,d}		
Operands:	$\begin{array}{l} 0 \leq k \leq 95 \\ d  \in  [0,1] \end{array}$

## 29.2.5 SPECIAL CONSIDERATIONS WITH MICROCHIP MPLAB<sup>®</sup> IDE TOOLS

The latest versions of Microchip's software tools have been designed to fully support the extended instruction set for the PIC18F97J94 Family. This includes the MPLAB C18 C Compiler, MPASM assembly language and MPLAB Integrated Development Environment (IDE).

When selecting a target device for software development, MPLAB IDE will automatically set default Configuration bits for that device. The default setting for the XINST Configuration bit is '1', enabling the extended instruction set and Indexed Literal Offset Addressing. For proper execution of applications developed to take advantage of the extended instruction set, XINST must be set during programming.

To develop software for the extended instruction set, the user must enable support for the instructions and the Indexed Addressing mode in their language tool(s). Depending on the environment being used, this may be done in several ways:

- A menu option or dialog box within the environment that allows the user to configure the language tool and its settings for the project
- A command-line option
- · A directive in the source code

These options vary between different compilers, assemblers and development environments. Users are encouraged to review the documentation accompanying their development systems for the appropriate information.

### 30.0 ELECTRICAL SPECIFICATIONS

### Absolute Maximum Ratings<sup>(†)</sup>

Ambient temperature under bias40°C to +100°C
Storage temperature
Voltage on MCLR with respect to Vss0.3V to 5.5V
Voltage on any digital only I/O pin with respect to Vss (except VDD)0.3V to 5.5V
Voltage on any combined digital and analog pin with respect to VSS (except VDD and MCLR)0.3V to (VDD + 0.3V)
Voltage on VBAT with respect to VSS
Voltage on VUSB3V3 with respect to VSS
Voltage on VDD with respect to Vss0.3V to 3.66V
Voltage on D+ or D- with respect to Vss – 0W source impedance (Note 2)0.5V to (VUSB3V3 + 0.5V)
Source impedance $\geq$ 28W, VUSB3V3 $\geq$ 3.0V)
Total power dissipation (Note 1)
Maximum current out of Vss pin
Maximum current into VDD pin
Input clamp current, Iικ (Vι < 0 or Vι > VDD)±20 mA
Output clamp current, IOK (VO < 0 or VO > VDD) ±20 mA
Maximum output current sunk by any I/O pins25 mA
Maximum output current sourced by any I/O pins25 mA
Maximum current sunk by all ports combined
Maximum current sourced by all ports combined

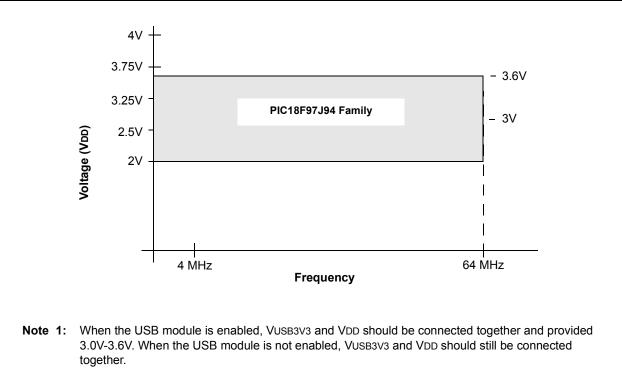

**Note 1:** Power dissipation is calculated as follows: Pdis = VDD x {IDD  $- \sum$  IOH} +  $\sum$  {(VDD - VOH) x IOH} +  $\sum$ (VOL x IOL)

2: The original "USB 2.0 Specification" indicated that USB devices should withstand 24-hour short circuits of D+ or D- to VBUS voltages. This requirement was later removed in an engineering change notice (ECN) supplement to the USB specifications, which supersedes the original specifications. PIC18FXXJ94 family devices will typically be able to survive this short circuit test, but it is recommended to adhere to the absolute maximum specified here to avoid damaging the device.

**NOTICE:** Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

+

2: VCAP (nominal on-chip regulator output voltage) = 1.8V.

D022 (ΔΙΗLVD)	High/Low-Voltage	4	8	μA	-40°C to +85°C	VDD = 2.0V					
	Detect	5	9	μA	-40°C to +85°C	VDD = 3.3V					
D023 (ΔIDSBOR)	Deep Sleep BOR	135	480	nA	-40°C to +85°C	VDD = 2.0V to 3.3V	ΔDeep Sleep BOR <sup>(2)</sup>				
D024 (ΔIDSWDT)	Deep Sleep Watchdog Timer	290	480	nA	-40°C to +85°C	VDD = 2.0V to 3.3V	ΔDeep Sleep WDT <sup>(2)</sup>				
D025 (Δloscb)	Real-Time Clock/ Calendar with Tim- er1 Oscillator	0.38	1	μA	-40°C to +85°C	VDD = 2.0V	Sleep mode 32.768 kHz, T1OSCEN = 1, LPT1OSC = 0				
		0.55	1	μA	-40°C to +85°C	VDD = 3.3V					
D027 (ΔILCD)	LCD Module	0.6	4	μA	-40°C to +85°C	VDD = 3.3V	ΔLCD External/Internal, 1/8 MUX, 1/3 Bias <sup>(2,3)</sup>				
		6	30	μA	-40°C to +85°C	VDD = 2.0V	ΔLCD Charge Pump,				
		7	40	μA	-40°C to +85°C	VDD = 3.3V	1/8 MUX, 1/3 Bias <sup>(2,4)</sup>				
D028 (ΔIADRC)	A/D with RC	330	500	μA	-40°C to +85°C	VDD = 2.0V					
		385	500	μA	-40°C to +85°C	VDD = 3.3V					
D028 (ΔIUSB)	USB Module	1	2	mA	-40°C to +85°C	VDD and VUSB3V3 = 3.3V	USB enabled, no cable con- nected; traffic makes a large dif- ference <sup>(5)</sup>				

Note 1: Data in the Typical column is at 3.3V, 25°C unless otherwise stated. Parameters are for design guidance only and are not tested.

2: Incremental current while the module is enabled and running.

- 3: LCD is enabled and running, no glass is connected; the resistor ladder current is not included.
- 4: LCD is enabled and running, no glass is connected.
- 5: This is the module differential current when the USB module is enabled and clocked at 48 MHz, but with no USB cable attached. When the USB cable is attached, or data is being transmitted, the current consumption may be much higher (see Section 27.6.4 "USB Transceiver Current Consumption"). During USB Suspend mode (USBEN = 1, SUSPND = 1, bus in Idle state), the USB module current will be dominated by the D+ or D- pull-up resistor. The integrated pull-up resistors use "resistor switching" according to the resistor\_ecn supplement to the "USB 2.0 Specification" and therefore, may be as low as 900Ω during Idle conditions.

D321	Vol	Voltage Output Low	0	—	0.3	V	1.5 k $\Omega$ load connected to 3.6V			
D322	Voн	Voltage Output High	2.8	—	3.6	V	1.5 k $\Omega$ load connected to ground			

### TABLE 30-16: USB MODULE SPECIFICATIONS

**Note 1:** The D+ and D- signal lines have built-in impedance matching resistors. No external resistors, capacitors or magnetic components are necessary on the D+/D- signal paths between the PIC18F97J94 family device and a USB cable.

### **30.1** AC (Timing) Characteristics

#### 30.1.1 TIMING PARAMETER SYMBOLOGY

The timing parameter symbols have been created following one of the following formats:

### TABLE 30-17: TIMING PARAMETER SYMBOLS

1. TppS2ppS		3. TCC:ST	(I <sup>2</sup> C specifications only)
2. TppS		4. Ts	(I <sup>2</sup> C specifications only)
Т			
F	Frequency	Т	Time
Lowercase	letters (pp) and their meanings:		
рр			
сс	CCP1	osc	OSC1
ck	CLKO	rd	RD
cs	CS	rw	RD or WR
di	SDI	sc	SCK
do	SDO	SS	SS
dt	Data in	tO	TOCKI
io	I/O port	t1	T1CKI
mc	MCLR	wr	WR
Uppercase	letters and their meanings:		
S			
F	Fall	Р	Period
Н	High	R	Rise
I	Invalid (High-impedance)	V	Valid
L	Low	Z	High-impedance
I <sup>2</sup> C only			
AA	output access	High	High
BUF	Bus free	Low	Low
TCC:ST (I <sup>2</sup> C	specifications only)	•	
CC			
HD	Hold	SU	Setup
ST			
DAT	DATA input hold	STO	Stop condition
STA	Start condition		

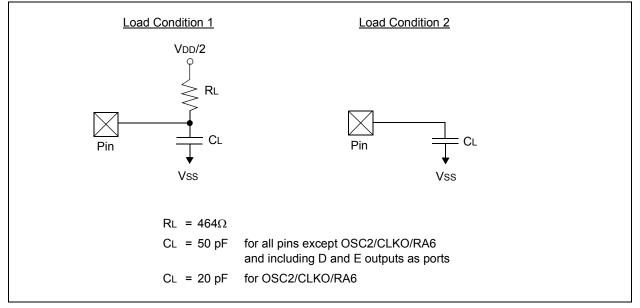

### 30.1.2 TIMING CONDITIONS

The temperature and voltages specified in Table 30-18 apply to all timing specifications unless otherwise noted. Figure 30-2 specifies the load conditions for the timing specifications.

#### TABLE 30-18: TEMPERATURE AND VOLTAGE SPECIFICATIONS - AC

	Standard Operating Conditions (unless otherwise stated)
AC CHARACTERISTICS	Operating temperature $-40^{\circ}C \le TA \le +85^{\circ}C$ for industrial
	Operating voltage VDD range as described in Section TABLE 30-1: and Section .

### FIGURE 30-2: LOAD CONDITIONS FOR DEVICE TIMING SPECIFICATIONS

### 30.1.3 TIMING DIAGRAMS AND SPECIFICATIONS

### FIGURE 30-3: EXTERNAL CLOCK TIMING

### TABLE 30-19: EXTERNAL CLOCK TIMING REQUIREMENTS

Param. No.	Symbol	Characteristic	Min.	Max.	Units	Conditions
1A	Fosc	External CLKIN Frequency <sup>(1)</sup>	DC	64	MHz	EC Oscillator mode
		Oscillator Frequency <sup>(1)</sup>	4	16	MHz	HS Oscillator mode
			4	16	MHz	HS + PLL Oscillator mode
1	Tosc	External CLKIN Period <sup>(1)</sup>	15.6	_	ns	EC, ECIO Oscillator mode
		Oscillator Period <sup>(1)</sup>	40	250	ns	HS Oscillator mode
			62.5	250	ns	HS+PLL Oscillator mode
2	Тсү	Instruction Cycle Time <sup>(1)</sup>	62.5	_	ns	Tcy = 4/Fosc
3	TosL, TosH	External Clock in (OSC1) High or Low Time	10	—	ns	HS Oscillator mode
4	TosR, TosF	External Clock in (OSC1) Rise or Fall Time	—	7.5	ns	HS Oscillator mode

**Note 1:** Instruction cycle period (TCY) equals four times the input oscillator time base period for all configurations except PLL. All specified values are based on characterization data for that particular oscillator type under standard operating conditions with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at "min." values with an external clock applied to the OSC1/CLKIN pin. When an external clock input is used, the "max." cycle time limit is "DC" (no clock) for all devices.

TABLE 30-20: 4/6/8x PLL CLOCK TIMING SPECIFICATIONS (VDD = 2.0V TO 3.6V) <sup>(1)</sup>
---

Param No.	Sym.	Characteristic	Min.	Тур.	Max.	Units	Conditions
F10	Fosc	Oscillator Frequency Range	4	_	16	MHz	VDD = 2.0-3.6V, -40°C to +85°C
F11	Fsys	On-Chip VCO System Frequency	16		64	MHz	VDD = 2.0-3.6V, -40°C to +85°C
F12	t <sub>rc</sub>	PLL Start-up Time (Lock Time)	-		2	ms

TABLE 30-35:	I <sup>2</sup> C BUS DATA	REQUIREMENTS	(SLAVE MODE)
--------------	---------------------------	--------------	--------------

**Note 1:** As a transmitter, the device must provide this internal minimum delay time to bridge the undefined region (min. 300 ns) of the falling edge of SCLx to avoid unintended generation of Start or Stop conditions.

2: A Fast mode I<sup>2</sup>C bus device can be used in a Standard mode I<sup>2</sup>C bus system, but the requirement, Tsu:DAT ≥ 250 ns, must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCLx signal. If such a device does stretch the LOW period of the SCLx signal, it must output the next data bit to the SDAx line, TR max. + Tsu:DAT = 1000 + 250 = 1250 ns (according to the Standard mode I<sup>2</sup>C bus specification), before the SCLx line is released.

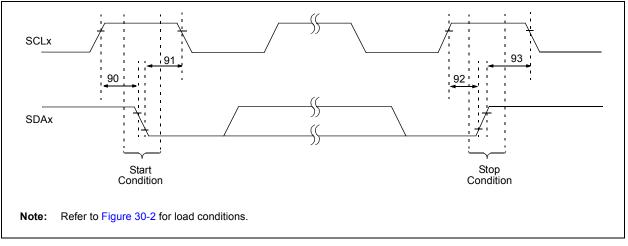

### TABLE 30-35: I<sup>2</sup>C BUS DATA REQUIREMENTS (SLAVE MODE)

Param. No.	Symbol	Characteristic	Min.	Max.	Units	Conditions
D102	Св	Bus Capacitive Loading	_	400	pF	

**Note 1:** As a transmitter, the device must provide this internal minimum delay time to bridge the undefined region (min. 300 ns) of the falling edge of SCLx to avoid unintended generation of Start or Stop conditions.

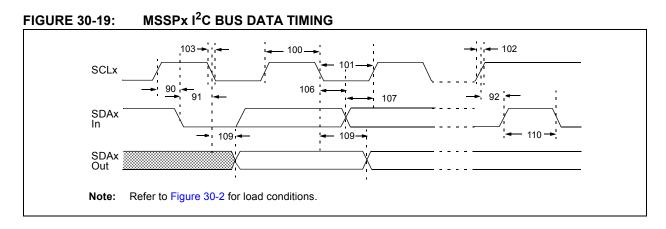

2: A Fast mode I<sup>2</sup>C bus device can be used in a Standard mode I<sup>2</sup>C bus system, but the requirement, Tsu:DAT ≥ 250 ns, must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCLx signal. If such a device does stretch the LOW period of the SCLx signal, it must output the next data bit to the SDAx line, TR max. + Tsu:DAT = 1000 + 250 = 1250 ns (according to the Standard mode I<sup>2</sup>C bus specification), before the SCLx line is released.

### FIGURE 30-18: MSSPx I<sup>2</sup>C BUS START/STOP BITS TIMING WAVEFORMS

A06	EOFF	Offset Error	_	<±1	±5	LSB	VDD = $3.0V (\Delta VREF \ge 2.0V)$
A07	Egn	Gain Error	_	<±1	±5	LSB	VDD = 3.0V ( $\Delta$ VREF $\geq$ 2.0V)
A10	—	Monotonicity <sup>(1)</sup>			•		$VSS \leq VAIN \leq VREF$
A20	$\Delta VREF$	Reference Voltage Range (VREFH – VREFL)	2	—	VDD – VSS	V	For 12-bit resolution
A21	VREFH	Reference Voltage High	AVss + 2.0V		AVDD + 0.3V	V	For 12-bit resolution
A22	VREFL	Reference Voltage Low	AVss – 0.3V		AVDD - 2.0V	V	For 12-bit resolution
A25	VAIN	Analog Input Voltage	VREFL		VREFH	V	
A28	AVDD	Analog Supply Voltage	VDD - 0.3		VDD + 0.3	V	
A29	AVss	Analog Supply Voltage	Vss – 0.3		Vss + 0.3	V	
A30	ZAIN	Recommended Impedance of Analog Voltage Source	_	_	2.5	kΩ	
A50	IREF	VREF Input Current <sup>(2)</sup>	—		5 150	μΑ μΑ	During VAIN acquisition. During A/D conversion cycle.

### TABLE 30-40: A/D CONVERTER CHARACTERISTICS:PIC18FXXJ94 (INDUSTRIAL)

Note 1: The A/D conversion result never decreases with an increase in the input voltage.

2: VREFH current is from the RA3/AN3/VREF+ pin or VDD, whichever is selected as the VREFH source. VREFL current is from the RA2/AN2/VREF-/CVREF pin or VSS, whichever is selected as the VREFL source.

### TABLE 30-41: A/D CONVERSION REQUIREMENTS

Param. No.	Symbol	Characteristic	Min.	Max.	Units	Conditions
		Sample Start Delay from Setting SAMP	2	3	TAD	
130	TAD	A/D Clock Period	300	_	ns	
			250	_	ns	A/D RC mode
131	TCNV	Conversion Time (not including acquisition time) <sup>(2)</sup>	14	15	Tad	
132	TACQ	Acquisition Time <sup>(3)</sup>		750	ns	-40°C to +85°C <sup>(5)</sup>
135	Tswc	Switching Time from Convert $\rightarrow$ Sample	_	(Note 4)		
	TDIS	Discharge Time	1	—	TAD	-40°C to +85°C
		A/D Stabilization Time (from setting ADON to setting SAMP)	300	—	ns	

Note 1: The time of the A/D clock period is dependent on the device frequency and the TAD clock divider.

2: ADRES registers may be read on the following TCY cycle.

**3:** The time for the holding capacitor to acquire the "New" input voltage when the voltage changes full scale after the conversion (VDD to Vss or Vss to VDD). The source impedance (*Rs*) on the input channels is 50Ω.

4: On the following cycle of the device clock.

**5:** The time for the holding capacitor to acquire the "New" input voltage when the voltage changes full scale after the conversion (AVDD to AVSS or AVSS to AVDD).

## 31.0 DEVELOPMENT SUPPORT

The PIC<sup>®</sup> microcontrollers (MCU) and dsPIC<sup>®</sup> digital signal controllers (DSC) are supported with a full range of software and hardware development tools:

- Integrated Development Environment
- MPLAB<sup>®</sup> X IDE Software
   Compilers/Assemblers/Linkers
- MPLAB XC Compiler
- MPASM<sup>™</sup> Assembler
- MPLINK<sup>™</sup> Object Linker/ MPLIB<sup>™</sup> Object Librarian
- MPLAB Assembler/Linker/Librarian for Various Device Families
- Simulators
  - MPLAB X SIM Software Simulator
- Emulators
  - MPLAB REAL ICE™ In-Circuit Emulator
- In-Circuit Debuggers/Programmers
  - MPLAB ICD 3
  - PICkit™ 3
- Device Programmers
  - MPLAB PM3 Device Programmer
- Low-Cost Demonstration/Development Boards, Evaluation Kits and Starter Kits
- Third-party development tools

## 31.1 MPLAB X Integrated Development Environment Software

The MPLAB X IDE is a single, unified graphical user interface for Microchip and third-party software, and hardware development tool that runs on Windows<sup>®</sup>, Linux and Mac  $OS^{®}$  X. Based on the NetBeans IDE, MPLAB X IDE is an entirely new IDE with a host of free software components and plug-ins for high-performance application development and debugging. Moving between tools and upgrading from software simulators to hardware debugging and programming tools is simple with the seamless user interface.

With complete project management, visual call graphs, a configurable watch window and a feature-rich editor that includes code completion and context menus, MPLAB X IDE is flexible and friendly enough for new users. With the ability to support multiple tools on multiple projects with simultaneous debugging, MPLAB X IDE is also suitable for the needs of experienced users.

Feature-Rich Editor:

- Color syntax highlighting
- Smart code completion makes suggestions and provides hints as you type
- Automatic code formatting based on user-defined rules
- · Live parsing

User-Friendly, Customizable Interface:

- Fully customizable interface: toolbars, toolbar buttons, windows, window placement, etc.
- · Call graph window
- Project-Based Workspaces:
- Multiple projects
- Multiple tools
- Multiple configurations
- · Simultaneous debugging sessions
- File History and Bug Tracking:
- Local file history feature
- Built-in support for Bugzilla issue tracker

## 31.2 MPLAB XC Compilers

The MPLAB XC Compilers are complete ANSI C compilers for all of Microchip's 8, 16, and 32-bit MCU and DSC devices. These compilers provide powerful integration capabilities, superior code optimization and ease of use. MPLAB XC Compilers run on Windows, Linux or MAC OS X.

For easy source level debugging, the compilers provide debug information that is optimized to the MPLAB X IDE.

The free MPLAB XC Compiler editions support all devices and commands, with no time or memory restrictions, and offer sufficient code optimization for most applications.

MPLAB XC Compilers include an assembler, linker and utilities. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. MPLAB XC Compiler uses the assembler to produce its object file. Notable features of the assembler include:

- · Support for the entire device instruction set
- · Support for fixed-point and floating-point data
- Command-line interface
- · Rich directive set
- · Flexible macro language
- MPLAB X IDE compatibility

## 31.3 MPASM Assembler

The MPASM Assembler is a full-featured, universal macro assembler for PIC10/12/16/18 MCUs.

The MPASM Assembler generates relocatable object files for the MPLINK Object Linker, Intel<sup>®</sup> standard HEX files, MAP files to detail memory usage and symbol reference, absolute LST files that contain source lines and generated machine code, and COFF files for debugging.

The MPASM Assembler features include:

- Integration into MPLAB X IDE projects
- User-defined macros to streamline assembly code
- Conditional assembly for multipurpose source files
- Directives that allow complete control over the assembly process

## 31.4 MPLINK Object Linker/ MPLIB Object Librarian

The MPLINK Object Linker combines relocatable objects created by the MPASM Assembler. It can link relocatable objects from precompiled libraries, using directives from a linker script.

The MPLIB Object Librarian manages the creation and modification of library files of precompiled code. When a routine from a library is called from a source file, only the modules that contain that routine will be linked in with the application. This allows large libraries to be used efficiently in many different applications.

The object linker/library features include:

- Efficient linking of single libraries instead of many smaller files
- Enhanced code maintainability by grouping related modules together
- Flexible creation of libraries with easy module listing, replacement, deletion and extraction

## 31.5 MPLAB Assembler, Linker and Librarian for Various Device Families

MPLAB Assembler produces relocatable machine code from symbolic assembly language for PIC24, PIC32 and dsPIC DSC devices. MPLAB XC Compiler uses the assembler to produce its object file. The assembler generates relocatable object files that can then be archived or linked with other relocatable object files and archives to create an executable file. Notable features of the assembler include:

- · Support for the entire device instruction set
- Support for fixed-point and floating-point data
- Command-line interface
- Rich directive set
- Flexible macro language
- MPLAB X IDE compatibility

## 31.6 MPLAB X SIM Software Simulator

The MPLAB X SIM Software Simulator allows code development in a PC-hosted environment by simulating the PIC MCUs and dsPIC DSCs on an instruction level. On any given instruction, the data areas can be examined or modified and stimuli can be applied from a comprehensive stimulus controller. Registers can be logged to files for further run-time analysis. The trace buffer and logic analyzer display extend the power of the simulator to record and track program execution, actions on I/O, most peripherals and internal registers.

The MPLAB X SIM Software Simulator fully supports symbolic debugging using the MPLAB XC Compilers, and the MPASM and MPLAB Assemblers. The software simulator offers the flexibility to develop and debug code outside of the hardware laboratory environment, making it an excellent, economical software development tool.

## 31.7 MPLAB REAL ICE In-Circuit Emulator System

The MPLAB REAL ICE In-Circuit Emulator System is Microchip's next generation high-speed emulator for Microchip Flash DSC and MCU devices. It debugs and programs all 8, 16 and 32-bit MCU, and DSC devices with the easy-to-use, powerful graphical user interface of the MPLAB X IDE.

The emulator is connected to the design engineer's PC using a high-speed USB 2.0 interface and is connected to the target with either a connector compatible with in-circuit debugger systems (RJ-11) or with the new high-speed, noise tolerant, Low-Voltage Differential Signal (LVDS) interconnection (CAT5).

The emulator is field upgradable through future firmware downloads in MPLAB X IDE. MPLAB REAL ICE offers significant advantages over competitive emulators including full-speed emulation, run-time variable watches, trace analysis, complex breakpoints, logic probes, a ruggedized probe interface and long (up to three meters) interconnection cables.

## 31.8 MPLAB ICD 3 In-Circuit Debugger System

The MPLAB ICD 3 In-Circuit Debugger System is Microchip's most cost-effective, high-speed hardware debugger/programmer for Microchip Flash DSC and MCU devices. It debugs and programs PIC Flash microcontrollers and dsPIC DSCs with the powerful, yet easy-to-use graphical user interface of the MPLAB IDE.

The MPLAB ICD 3 In-Circuit Debugger probe is connected to the design engineer's PC using a highspeed USB 2.0 interface and is connected to the target with a connector compatible with the MPLAB ICD 2 or MPLAB REAL ICE systems (RJ-11). MPLAB ICD 3 supports all MPLAB ICD 2 headers.

## 31.9 PICkit 3 In-Circuit Debugger/ Programmer

The MPLAB PICkit 3 allows debugging and programming of PIC and dsPIC Flash microcontrollers at a most affordable price point using the powerful graphical user interface of the MPLAB IDE. The MPLAB PICkit 3 is connected to the design engineer's PC using a fullspeed USB interface and can be connected to the target via a Microchip debug (RJ-11) connector (compatible with MPLAB ICD 3 and MPLAB REAL ICE). The connector uses two device I/O pins and the Reset line to implement in-circuit debugging and In-Circuit Serial Programming<sup>™</sup> (ICSP<sup>™</sup>).

## 31.10 MPLAB PM3 Device Programmer

The MPLAB PM3 Device Programmer is a universal, CE compliant device programmer with programmable voltage verification at VDDMIN and VDDMAX for maximum reliability. It features a large LCD display (128 x 64) for menus and error messages, and a modular, detachable socket assembly to support various package types. The ICSP cable assembly is included as a standard item. In Stand-Alone mode, the MPLAB PM3 Device Programmer can read, verify and program PIC devices without a PC connection. It can also set code protection in this mode. The MPLAB PM3 connects to the host PC via an RS-232 or USB cable. The MPLAB PM3 has high-speed communications and optimized algorithms for quick programming of large memory devices, and incorporates an MMC card for file storage and data applications.

## 31.11 Demonstration/Development Boards, Evaluation Kits, and Starter Kits

A wide variety of demonstration, development and evaluation boards for various PIC MCUs and dsPIC DSCs allows quick application development on fully functional systems. Most boards include prototyping areas for adding custom circuitry and provide application firmware and source code for examination and modification.

The boards support a variety of features, including LEDs, temperature sensors, switches, speakers, RS-232 interfaces, LCD displays, potentiometers and additional EEPROM memory.

The demonstration and development boards can be used in teaching environments, for prototyping custom circuits and for learning about various microcontroller applications.

In addition to the PICDEM<sup>™</sup> and dsPICDEM<sup>™</sup> demonstration/development board series of circuits, Microchip has a line of evaluation kits and demonstration software for analog filter design, KEELOQ<sup>®</sup> security ICs, CAN, IrDA<sup>®</sup>, PowerSmart battery management, SEEVAL<sup>®</sup> evaluation system, Sigma-Delta ADC, flow rate sensing, plus many more.

Also available are starter kits that contain everything needed to experience the specified device. This usually includes a single application and debug capability, all on one board.

Check the Microchip web page (www.microchip.com) for the complete list of demonstration, development and evaluation kits.

## 31.12 Third-Party Development Tools

Microchip also offers a great collection of tools from third-party vendors. These tools are carefully selected to offer good value and unique functionality.

- Device Programmers and Gang Programmers from companies, such as SoftLog and CCS
- Software Tools from companies, such as Gimpel and Trace Systems
- Protocol Analyzers from companies, such as Saleae and Total Phase
- Demonstration Boards from companies, such as MikroElektronika, Digilent<sup>®</sup> and Olimex
- Embedded Ethernet Solutions from companies, such as EZ Web Lynx, WIZnet and IPLogika<sup>®</sup>

## 32.0 DC AND AC CHARACTERISTICS GRAPHS AND CHARTS

The graphs and tables provided in this section are for **design guidance** and are **not tested**.

In some graphs or tables, the data presented are **outside specified operating range** (i.e., outside specified VDD range). This is for **information only** and devices are ensured to operate properly only within the specified range.

Unless otherwise noted, all graphs apply to both the L and LF devices.

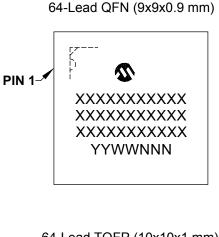

**Note:** The graphs and tables provided following this note are a statistical summary based on a limited number of samples and are provided for informational purposes only. The performance characteristics listed herein are not tested or guaranteed. In some graphs or tables, the data presented may be outside the specified operating range (e.g., outside specified power supply range) and therefore, outside the warranted range.

"Typical" represents the mean of the distribution at 25°C. "Maximum", "Max.", "Minimum" or "Min." represents (mean +  $3\sigma$ ) or (mean -  $3\sigma$ ) respectively, where  $\sigma$  is a standard deviation, over each temperature range.

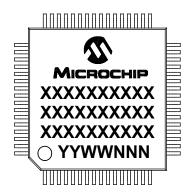

Charts and graphs are not available at this time.

## 33.0 PACKAGING INFORMATION

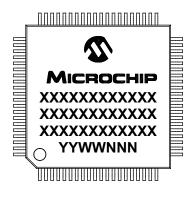

## 33.1 Package Marking Information

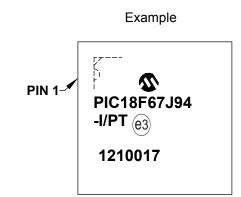

64-Lead TQFP (10x10x1 mm)

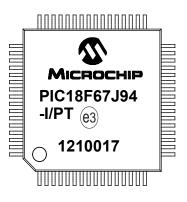

80-Lead TQFP (12x12x1 mm)

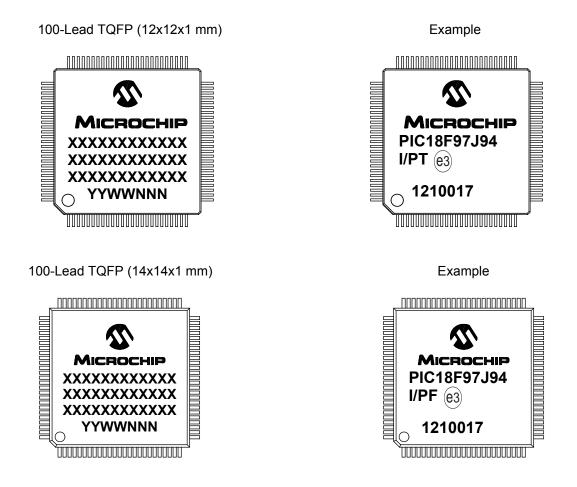

Example

Example

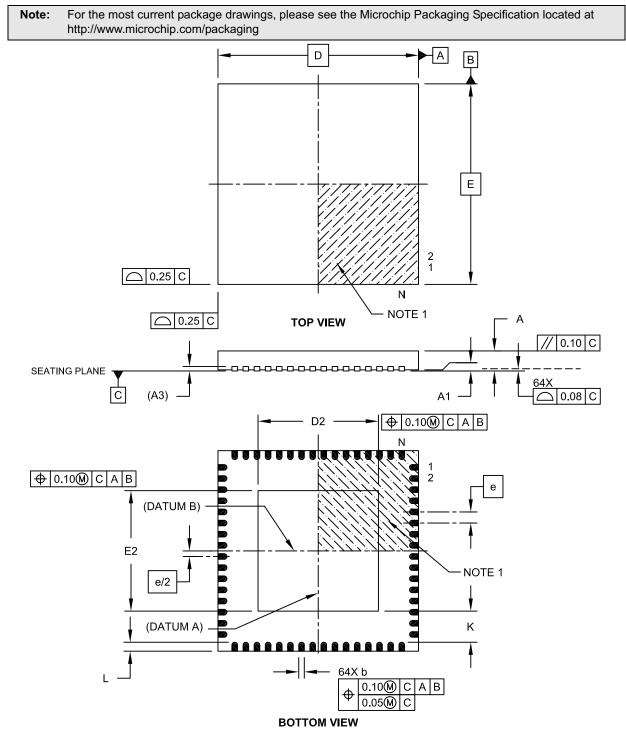

Legend	d: XXX Y YY WW NNN ≠ €3	Customer-specific information Year code (last digit of calendar year) Year code (last 2 digits of calendar year) Week code (week of January 1 is week '01') Alphanumeric traceability code Pb-free JEDEC <sup>®</sup> designator for Matte Tin (Sn) This package is Pb-free. The Pb-free JEDEC <sup>®</sup> designator (e3) can be found on the outer packaging for this package.
Note:	be carrie	nt the full Microchip part number cannot be marked on one line, it will d over to the next line, thus limiting the number of available s for customer-specific information.

## 33.2 Package Details

The following sections give the technical details of the packages.

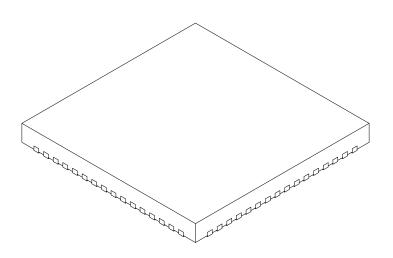

# 64-Lead Plastic Quad Flat, No Lead Package (MR) – 9x9x0.9 mm Body with 5.40 x 5.40 Exposed Pad [QFN]

1. Pin 1 visual index feature may vary, but must be located within the hatched area.

2. Chamfers at corners are optional; size may vary.

3. Dimensions D1 and E1 do not include mold flash or protrusions. Mold flash or protrusions shall not exceed 0.25 mm per side.

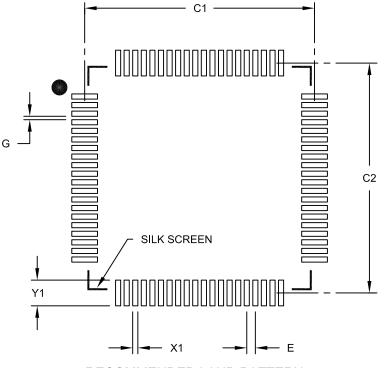

- 4. Dimensioning and tolerancing per ASME Y14.5M.
  - BSC: Basic Dimension. Theoretically exact value shown without tolerances.

REF: Reference Dimension, usually without tolerance, for information purposes only.

Microchip Technology Drawing C04-100B

100-Lead Plastic Thin Quad Flatpack (PT)-12x12x1mm Body, 2.00 mm Footprint [TQFP]

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at http://www.microchip.com/packaging

	MILLIMETERS				
Dimension	Dimension Limits		NOM	MAX	
Contact Pitch	Contact Pitch E		0.40 BSC		
Contact Pad Spacing	C1		13.40		
Contact Pad Spacing	C2		13.40		
Contact Pad Width (X100)	X1			0.20	
Contact Pad Length (X100)	Y1			1.50	
Distance Between Pads	G	0.20			

Notes:

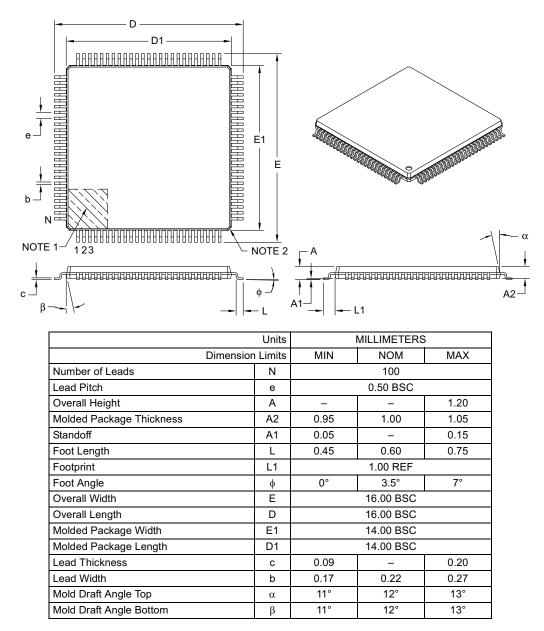

1. Dimensioning and tolerancing per ASME Y14.5M

BSC: Basic Dimension. Theoretically exact value shown without tolerances.

Microchip Technology Drawing No. C04-2100B

## 100-Lead Plastic Thin Quad Flatpack (PF) – 14x14x1 mm Body, 2.00 mm [TQFP]

**Note:** For the most current package drawings, please see the Microchip Packaging Specification located at http://www.microchip.com/packaging

#### Notes:

## APPENDIX A: REVISION HISTORY

## **Revision A (October 2012)**

This is the initial release of the document.

## **Revision B (08/2016)**

Updated data sheet to new format. Added corrections as per *PIC18F97J94 Family Silicon Errata and Data Sheet Clarifications* (DS8000551D), as follows: Updated Table 1; Added Table 2, Table 3 and Table 4; Updated Tables 1-4, 3-3, 6-2, 11-3, 11-6, 22-1; Added Table 30-18; Updated Register 4-8; Added Register 22-26; Updated Figures 11-7 and 22-1; Updated Examples 11-6, 22-1 and 22-2; Updated Equation 22-1. Update Packaging Information chapter. Other corrections.

## **Revision C (08/2016)**

Remove Preliminary status from data sheet.

## THE MICROCHIP WEBSITE

Microchip provides online support via our website site at www.microchip.com. This website is used as a means to make files and information easily available to customers. Accessible by using your favorite Internet browser, the website contains the following information:

- **Product Support** Data sheets and errata, application notes and sample programs, design resources, user's guides and hardware support documents, latest software releases and archived software
- General Technical Support Frequently Asked Questions (FAQ), technical support requests, online discussion groups, Microchip consultant program member listing
- Business of Microchip Product selector and ordering guides, latest Microchip press releases, listing of seminars and events, listings of Micro-chip sales offices, distributors and factory representatives

# CUSTOMER CHANGE NOTIFICATION SERVICE

Microchip's customer notification service helps keep customers current on Microchip products. Subscribers will receive e-mail notification whenever there are changes, updates, revisions or errata related to a specified product family or development tool of interest.

To register, access the Microchip website at www.microchip.com. Under "Support", click on "Customer Change Notification" and follow the registration instructions.

## **CUSTOMER SUPPORT**

Users of Microchip products can receive assistance through several channels:

- Distributor or Representative
- Local Sales Office
- Field Application Engineer (FAE)
- Technical Support

Customers should contact their distributor, representative or Field Application Engineer (FAE) for support. Local sales offices are also available to help customers. A listing of sales offices and locations is included in the back of this document.

Technical support is available through the website at: http://microchip.com/support.

## **PRODUCT IDENTIFICATION SYSTEM**

To order or obtain information, e.g., on pricing or delivery, refer to the factory or the listed sales office.

PART NO.	<u>[X]</u> <sup>(1)</sup>	¥	<u>/XX</u>	<u>xx</u>	<u>(X</u>	Exa	mples:
Device	Tape and Reel Option	Temperature Range	Package	Patt	ern	a) b)	PIC18F97J94-I/PT = Industrial temp., TQFP package, QTP pattern #301. PIC18F87J94-I/PT = Industrial temp., TQFP package.
Device:	PIC18F97J94, PIC PIC18F86J94, PIC PIC18F65J94 VDD range 2.0 to 3.	18F85J94, PIC18F					
Tape and Reel Option:	Blank = Standard T = Tape and	l packaging (tube d d Reel <sup>(1)</sup>	or tray)				
Temperature Range:	I = $-40^{\circ}$ C to	+85°C (Indus	trial)				
Package:	PT = TQFP PF = TQFP	(Thin Quad Flatpa (100-Pin Thin Qua	ck) id, 14x14x1 Bi	ody)		Note	Tape and Reel identifier only appears in the catalog part number description. This identifier is used for ordering purposes and is not printed on the device package. Check
Pattern:	QTP, SQTP, Code o (blank otherwise)	or Special Require	ments				with your Microchip Sales Office for package availability with the Tape and Reel option.

#### Note the following details of the code protection feature on Microchip devices:

- · Microchip products meet the specification contained in their particular Microchip Data Sheet.
- Microchip believes that its family of products is one of the most secure families of its kind on the market today, when used in the intended manner and under normal conditions.
- There are dishonest and possibly illegal methods used to breach the code protection feature. All of these methods, to our knowledge, require using the Microchip products in a manner outside the operating specifications contained in Microchip's Data Sheets. Most likely, the person doing so is engaged in theft of intellectual property.
- Microchip is willing to work with the customer who is concerned about the integrity of their code.
- Neither Microchip nor any other semiconductor manufacturer can guarantee the security of their code. Code protection does not mean that we are guaranteeing the product as "unbreakable."

Code protection is constantly evolving. We at Microchip are committed to continuously improving the code protection features of our products. Attempts to break Microchip's code protection feature may be a violation of the Digital Millennium Copyright Act. If such acts allow unauthorized access to your software or other copyrighted work, you may have a right to sue for relief under that Act.

Information contained in this publication regarding device applications and the like is provided only for your convenience and may be superseded by updates. It is your responsibility to ensure that your application meets with your specifications. MICROCHIP MAKES NO REPRESENTATIONS OR WARRANTIES OF ANY KIND WHETHER EXPRESS OR IMPLIED, WRITTEN OR ORAL, STATUTORY OR OTHERWISE, RELATED TO THE INFORMATION, INCLUDING BUT NOT LIMITED TO ITS CONDITION, QUALITY, PERFORMANCE, MERCHANTABILITY OR FITNESS FOR PURPOSE. Microchip disclaims all liability arising from this information and its use. Use of Microchip devices in life support and/or safety applications is entirely at the buyer's risk, and the buyer agrees to defend, indemnify and hold harmless Microchip from any and all damages, claims, suits, or expenses resulting from such use. No licenses are conveyed, implicitly or otherwise, under any Microchip intellectual property rights unless otherwise stated.

Microchip received ISO/TS-16949:2009 certification for its worldwide headquarters, design and wafer fabrication facilities in Chandler and Tempe, Arizona; Gresham, Oregon and design centers in California and India. The Company's quality system processes and procedures are for its PIC® MCUs and dsPIC® DSCs, KEELoQ® code hopping devices, Serial EEPROMs, microperipherals, nonvolatile memory and analog products. In addition, Microchip's quality system for the design and manufacture of development systems is ISO 9001:2000 certified.

## QUALITY MANAGEMENT SYSTEM CERTIFIED BY DNV = ISO/TS 16949=

#### Trademarks

The Microchip name and logo, the Microchip logo, AnyRate, dsPIC, FlashFlex, flexPWR, Heldo, JukeBlox, KeeLoq, KeeLoq logo, Kleer, LANCheck, LINK MD, MediaLB, MOST, MOST logo, MPLAB, OptoLyzer, PIC, PICSTART, PIC32 logo, RightTouch, SpyNIC, SST, SST Logo, SuperFlash and UNI/O are registered trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

ClockWorks, The Embedded Control Solutions Company, ETHERSYNCH, Hyper Speed Control, HyperLight Load, IntelliMOS, mTouch, Precision Edge, and QUIET-WIRE are registered trademarks of Microchip Technology Incorporated in the U.S.A.

Analog-for-the-Digital Age, Any Capacitor, AnyIn, AnyOut, BodyCom, chipKIT, chipKIT logo, CodeGuard, dsPICDEM, dsPICDEM.net, Dynamic Average Matching, DAM, ECAN, EtherGREEN, In-Circuit Serial Programming, ICSP, Inter-Chip Connectivity, JitterBlocker, KleerNet, KleerNet logo, MiWi, motorBench, MPASM, MPF, MPLAB Certified logo, MPLIB, MPLINK, MultiTRAK, NetDetach, Omniscient Code Generation, PICDEM, PICDEM.net, PICkit, PICtail, PureSilicon, RightTouch logo, REAL ICE, Ripple Blocker, Serial Quad I/O, SQI, SuperSwitcher, SuperSwitcher II, Total Endurance, TSHARC, USBCheck, VariSense, ViewSpan, WiperLock, Wireless DNA, and ZENA are trademarks of Microchip Technology Incorporated in the U.S.A. and other countries.

SQTP is a service mark of Microchip Technology Incorporated in the U.S.A.

Silicon Storage Technology is a registered trademark of Microchip Technology Inc. in other countries.

GestIC is a registered trademark of Microchip Technology Germany II GmbH & Co. KG, a subsidiary of Microchip Technology Inc., in other countries.

All other trademarks mentioned herein are property of their respective companies.
